Non-classical search algorithms

Chapter 4

Outline

- ♦ Hill-climbing
- ♦ Simulated annealing (briefly)
- $\diamondsuit \ \ \text{Genetic algorithms (briefly)}$
- ♦ Local search in continuous spaces (briefly)
- \diamondsuit (NEW!) Searching with nondeterministic actions (briefly)
- ♦ (NEW!) Searching with partial observations (briefly)
- ♦ (NEW!) Online search and unknown environments (briefly)

Iterative improvement algorithms

In many optimization problems, ${\color{blue}path}$ is irrelevant; the goal state itself is the solution

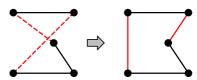

Then state space = set of "complete" configurations; find optimal configuration, e.g., TSP or, find configuration satisfying constraints, e.g., timetable

In such cases, can use iterative improvement algorithms; keep a single "current" state, try to improve it

Constant space, suitable for online as well as offline search

Example: Travelling Salesperson Problem

Start with any complete tour, perform pairwise exchanges

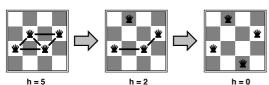

Variants of this approach get within 1% of optimal very quickly with thousands of cities

Sizeri Randi Oqfor 4 3 © Shari Randi Oqfor 4

Example: n-queens

Put n queens on an $n\times n$ board with no two queens on the same row, column, or diagonal

Move a queen to reduce number of conflicts

Almost always solves $n\text{-}\mathrm{queens}$ problems almost instantaneously for very large n, e.g., n=1million

Hill-climbing (or gradient ascent/descent)

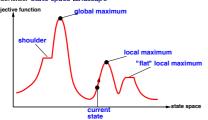

"Like dimbing Everest in thick fog with amnesia"

```
function HILL-CLIMBING (problem) returns a state that is a local maximum inputs: problem, a problem local variables: current, a node neighbor, a node current← MAKE-NODE(INITIAL-STATE[problem]) loop do neighbor ← a highest-valued successor of current if VALUE[neighbor] ≤ VALUE[current] then return STATE[current] current← neighbor end
```

Hill-climbing contd.

Useful to consider state space landscape

Random-restart hill climbing overcomes local maxima—trivially complete

Random sideways moves escape from shoulders loop on flat maxima

© Staart Ranell Chapter 4

Simulated annealing

Idea: escape local maxima by allowing some "bad" moves but gradually decrease their size and frequency

```
Function SIMULATED-ANNEALING ( problem, schedule ) returns a solution state inputs: problem, a problem schedule, a mapping from time to "temperature" local variables: current, a node neat, a node T, a "temperature" controlling prob. of downward steps T and T and T and T and T are schedule T and
```

Properties of simulated annealing

At fixed 'temperature' $T,\,\mathrm{state}$ occupation probability reaches Boltzman distribution

$$p(x) = \alpha e^{\frac{E(x)}{kT}}$$

 $\begin{array}{l} T \text{ decreased slowly enough} \Longrightarrow \text{always reach best state } x^* \\ \text{because } e^{\frac{E(x^*)}{kT}}/e^{\frac{E(x)}{kT}} = e^{\frac{E(x^*)-E(x)}{kT}} \gg 1 \text{ for small } T \end{array}$

Is this necessarily an interesting guarantee??

Devised by Metropolis et al., 1953, for physical process modelling

Widely used in VLSI layout, airline scheduling, etc.

Local beam search

Idea: keep k states instead of 1; choose top k of all their successors

Not the same as k searches run in parallel!

Searches that find good states recruit other searches to join them

Problem: quite often, all \boldsymbol{k} states end up on same local hill

Idea: choose \boldsymbol{k} successors randomly, biased towards good ones

Observe the close analogy to natural selection!

Start litted Oqur 4 9 Shart litted Oqur 4

Genetic algorithms

= stochastic local beam search + generate successors from \mathbf{pairs} of states

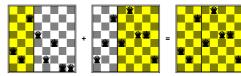

Fitness Selection Pairs Cross-Over Mutation

Genetic algorithms contd.

GAs require states encoded as strings (GPs use programs)

Crossover helps iff substrings are meaningful components

GAs \neq evolution: e.g., real genes encode replication machinery!

Continuous state spaces

Suppose we want to site three airports in Romania:

- 6-D state space defined by (x_1,y_2) , (x_2,y_2) , (x_3,y_3) objective function $f(x_1,y_2,x_2,y_2,x_3,y_3) =$

sum of squared distances from each city to nearest airport

Discretization methods turn continuous space into discrete space, e.g., empirical gradient considers $\pm \delta$ change in each coordinate

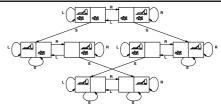

Gradient methods compute

$$\nabla f = \left(\frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial y_1}, \frac{\partial f}{\partial x_2}, \frac{\partial f}{\partial y_2}, \frac{\partial f}{\partial x_3}, \frac{\partial f}{\partial y_3}\right)$$

to increase/reduce f , e.g., by $\mathbf{x} \leftarrow \mathbf{x} + \alpha \nabla f(\mathbf{x})$

Sometimes can solve for $\nabla f(\mathbf{x})=0$ exactly (e.g., with one city). Newton–Raphson (1664, 1690) iterates $\mathbf{x}\leftarrow\mathbf{x}-\mathbf{H}_f^{-1}(\mathbf{x})\nabla f(\mathbf{x})$ to solve $\nabla f(\mathbf{x})=0$, where $\mathbf{H}_{ij}\!=\!\partial^2 f/\partial x_i\partial x_j$

Searching with nondeterministic actions

Erratic vacuum world: modified Suck;

Slippery vacuum world: modified Right and Left.

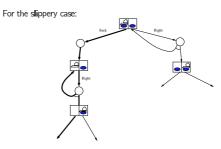

Searching with nondeterministic actions

And-or search trees

For the erratic case:

Searching with nondeterministic actions

And-or search trees

Searching with nondeterministic actions

function And-Or-Graph-Search(problem) returns a cond. plan, or failure OR-SEARCH(problem.Initial-State,problem,[])

function Or-Search(state,problem,path) returns a conditional plan or failure if problem.Goal-Test(state) then return the empty plan In procent_GOAL=TEST(state) then return the empty pan if state is on path then return failure for each action in problem.ACTIONS(state) do plan←AND-SEARCH(RESULTS(state,action), problem,[state | path]) if plan≠ failure then return [action | plan]

function And-Search (states,problem,path) returns a conditional plan or failurefor each s_i in states do $plan_i \leftarrow \operatorname{OR-SEARCH}(s_i, problem, path)$ if $plan_i = faihure$ then return faihure return $[if s_1$ then $plan_1$ else if s_2 then $plan_2$ else if ... $plan_{n-1}$ else $plan_n$]

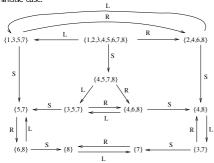

Searching with partial observations

- ♦ no-information case: sensorless problem, or conformant problem
- \Diamond state-space search is made in **belief space**
- ♦ Problem solving: and-or search!

Chapter 4 18 © Stuart Record

Searching with partial observations

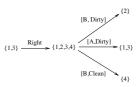

Deterministic case:

Searching with partial observations

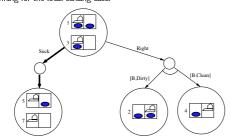

Local sensing, deterministic and slippery cases:

Searching with partial observations

Planning for the local sensing case:

Interleaving computations and actions: $\Diamond \ \, \mathsf{act}$

♦ observe the results

 \diamondsuit find out (compute) next action

Useful in dynamic domains.

Online search usually exploits locality of depth-first-like methods.

Online search and unknown environments

 \Diamond random walk

♦ modified hill-climbing

♦ Learning Real-Time A* (LRTA*)

optimism under uncertainty (unexplored areas assumed to lead to goal with least possible cost)
