# PROBLEM SOLVING AND SEARCH BY STUART RUSSELL

# Modified by Jacek Malec for LTH lectures ${\rm January~24th,~2013}$

Chapter 3 of AIMA

#### Outline

- ♦ Problem-solving agents
- ♦ Problem types
- ♦ Problem formulation
- ♦ Example problems
- $\Diamond$  Basic (uninformed) search algorithms
- ♦ Informed search algorithms

### Problem-solving agents

Restricted form of general agent:

function SIMPLE-PROBLEM-SOLVING-AGENT( percept) returns an action static: seq, an action sequence, initially empty state, some description of the current world state goad, a goal, initially null problem, a problem formulation state ← UPDATE-STATE(state, percept) if seq is empty then goal ← FORMULATE-GOAL(state) problem ← FORMULATE-PROBLEM(state, goal) seq ← SEARCH( problem) action ← RECOMMENDATION(seq, state) seq ← REMAINDER(seq, state) return action

Note: this is offline problem solving; solution executed "eyes closed." Online problem solving involves acting without complete knowledge.

Example: Blocket

 $@ Jorchr \ / \ Wikimedia \ Commons \ / \ CC-BY-SA-3.0 \ / \ GFDL$ 

UL TRIBUT CAPPORT 30 / AMAN A 3 (S. STADET RESSET) CAPPORT 30 / AMAN A

# Example: Blocket

Service robot Odin, delivering drugs to divisions. Currently in the Pharmacy. There is a drug order from Intensive Care Unit.

Formulate goal:

be in Intensive Care Unit

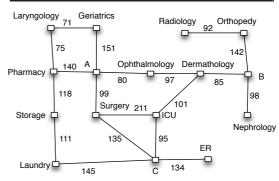

Formulate problem:

states: various locations actions: drive between locations

Find solution:

sequence of locations, e.g., Pharmacy, Elevator A, Surgery, ICU

# Example: Blocket

#### Problem types

Deterministic, fully observable  $\Longrightarrow$  single-state problem Agent knows exactly which state it will be in; solution is a sequence

Non-observable  $\Longrightarrow$  conformant problem

Agent may have no idea where it is; solution (if any) is a sequence

Nondeterministic and/or partially observable ⇒ contingency problem percepts provide new information about current state solution is a contingent plan or a policy often interleave search, execution

Unknown state space  $\Longrightarrow$  exploration problem ("online")

#### Example: vacuum world

Single-state, start in #5. Solution??

Chapter 3 of AIMA 7

#### Example: vacuum world

Single-state, start in #5. Solution?? [Right, Suck]

Conformant, start in  $\{1,2,3,4,5,6,7,8\}$  e.g., Right goes to  $\{2,4,6,8\}$ . Solution??

Example: vacuum world

Single-state, start in #5. Solution??

[Right, Suck]

Conformant, start in  $\{1,2,3,4,5,6,7,8\}$ e.g., Right goes to {2,4,6,8}. Solution?? [Right, Suck, Left, Suck]

Contingency, start in #5

Murphy's Law: Suck can dirty a clean carpet Local sensing: dirt, location only. Solution??

pter 3 of AIMA 8

Chapter 3 of AIMA 9 Chapter 3 of ADAA 10

# Example: vacuum world

Single-state, start in #5. Solution?? [Right, Suck]

 $\begin{array}{ll} \textbf{Conformant, start in} \ \{1,2,3,4,5,6,7,8\} \\ \textbf{e.g.,} \ Right \ \textbf{goes to} \ \{2,4,6,8\}. \ \ \underline{\textbf{Solution}} \ref{Solution} \\ [Right, Suck, Left, Suck] \end{array}$ 

Contingency, start in #5Murphy's Law: Suck can dirty a clean carpet Local sensing: dirt, location only. Solution??

 $[Right, \mathbf{if}\ dirt\ \mathbf{then}\ Suck]$ 

A problem is defined by four items:

initial state e.g., "at Pharmacy"

successor function  $S(x) = \operatorname{set}$  of action–state pairs

 $\textbf{e.g.,} \ S(Pharmacy) = \{ \langle Pharmacy \rightarrow Storage, Storage \rangle, \ldots \}$ 

Single-state problem formulation

goal test, can be

explicit, e.g., x= "at ICU" implicit, e.g., NoDirt(x)

path cost (additive)

e.g., sum of distances, number of actions executed, etc. c(x,a,y) is the step cost, assumed to be  $\geq 0$ 

A solution is a sequence of actions leading from the initial state to a goal state

#### Selecting a state space

Real world is absurdly complex

⇒ state space must be abstracted for problem solving

(Abstract) state = set of real states

(Abstract) action = complex combination of real actions e.g., "Pharmacy → Storage" represents a complex set of possible routes, detours, rest stops, etc.

For guaranteed realizability, any real state "in Pharmacy" must get to some real state "in Storage"

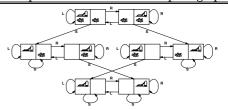

(Abstract) solution =

set of real paths that are solutions in the real world

Each abstract action should be "easier" than the original problem!

Steart Renell Chapter 3 of AIMA 1

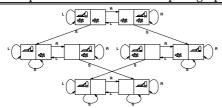

#### Example: vacuum world state space graph

# Example: vacuum world state space graph

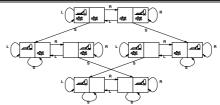

states??: integer dirt and robot locations (ignore dirt amounts etc.)
actions??: Left, Right, Suck, NoOp
goal test??
path cost??

gat Russell Clastict 3 of ADA 16

# Example: vacuum world state space graph

 $\begin{tabular}{ll} {\bf states??:} & integer dirt and robot locations (ignore dirt amounts etc.) \\ {\bf actions??:} & Left, Right, Suck, NoOp \\ \end{tabular}$ 

goal test??: no dirt

path cost??

# Example: vacuum world state space graph

states??: integer dirt and robot locations (ignore dirt amounts etc.)

actions??: Left, Right, Suck, NoOp

goal test?? no dirt

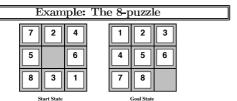

path cost??: 1 per action (0 for NoOp)

#### 

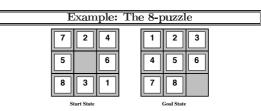

states?? actions?? goal test?? path cost??

Example: The 8-puzzle 7 2 2 4 1 3 5 6 4 5 6 3 8 1 7 8

states??: integer locations of tiles (ignore intermediate positions)
actions??
goal test??
path cost??

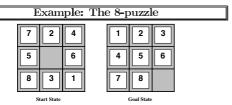

states??: integer locations of tiles (ignore intermediate positions) actions??: move blank left, right, up, down (ignore unjamming etc.) goal test??
path cost??

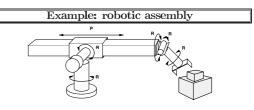

states??: integer locations of tiles (ignore intermediate positions)
actions??: move blank left, right, up, down (ignore unjamming etc.)
goal test??: = goal state (given)
path cost??

Chapter 3 of ADAA 21 © Sharet Rissell Chapter 3 of ADAA 22

states??: integer locations of tiles (ignore intermediate positions)
actions??: move blank left, right, up, down (ignore unjamming etc.)
goal test??: = goal state (given)
path cost??: 1 per move

[Note: optimal solution of  $n ext{-}\text{Puzzle}$  family is NP-hard]

states??: real-valued coordinates of robot joint angles
parts of the object to be assembled

actions??: continuous motions of robot joints

goal test??: complete assembly with no robot included!

path cost??: time to execute

#### Tree search algorithms

#### Basic idea:

offline, simulated exploration of state space by generating successors of already-explored states (a.k.a. expanding states)

function TREE-SEARCH(problem, strategy) returns a solution, or failure initialize the search tree using the initial state of problem loop do if there are no candidates for expansion then return failure choose a leaf node for expansion according to strategy if the node contains a goal state then return the corresponding solution else expand the node and add the resulting nodes to the search tree

#### Tree search example

© Steast Based Capter 3 of ABAA 25 © Shoart Rased Capter 3 of ABAA

#### Tree search example

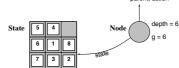

#### Tree search example

# Implementation: states vs. nodes

A state is a (representation of) a physical configuration A node is a data structure constituting part of a search tree includes parent, children, depth, path cost g(x) States do not have parents, children, depth, or path cost! parent, action

The  $\rm EXPAND$  function creates new nodes, filling in the various fields and using the  $\rm SUCCESSORFN$  of the problem to create the corresponding states.

# Implementation: general tree search

```
function TREE-SEARCH(problem, fringe) returns a solution, or failure fringe ← INSERT(MAKE-NODE(INITIAL-STATE[problem]), fringe) loop do

if fringe is empty then return failure

node ← REMOVE-FRONT(fringe)

if GOAL-TEST(problem, STATE(node)) then return node fringe ← INSERTALL(EXPAND(node, problem), fringe)

function EXPAND(node, problem) returns a set of nodes

successors ← the empty set

for each action, result in SUCCESSOR-FN(problem, STATE[node]) do

s ← a new NODE

PARENT-NODE[s] ← node, ACTION[s] ← action; STATE[s] ← result

PATH-COST[s] ← PATH-COST[node] + STEP-COST(STATE[node], action, result)

DEPTH[s] ← DEPTH[node] + 1

add s to successors

return successors
```

#### Search strategies

A strategy is defined by picking the order of node expansion

Strategies are evaluated along the following dimensions: completeness—does it always find a solution if one exists? time complexity—number of nodes generated/expanded space complexity—maximum number of nodes in memory optimality—does it always find a least-cost solution?

Time and space complexity are measured in terms of b—maximum branching factor of the search tree d—depth of the least-cost solution m—maximum depth of the state space (may be  $\infty$ )

#### Uninformed search strategies

Uninformed strategies use only the information available in the problem definition

Sometimes called **blind** search strategies

Breadth-first search

Uniform-cost search

Depth-first search

Depth-limited search

Iterative deepening search

Chapter 3 of AIMA 32

### Breadth-first search

Expand shallowest unexpanded node

#### Implementation:

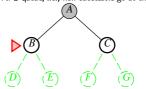

### Breadth-first search

Expand shallowest unexpanded node

#### ${\bf Implementation:}$

 $\ensuremath{\textit{fringe}}$  is a FIFO queue, i.e., new successors go at end

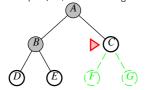

Chapter 3 of AIMA 34

# Breadth-first search

Expand shallowest unexpanded node

# Implementation:

fringe is a FIFO queue, i.e., new successors go at end

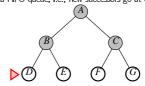

# Breadth-first search

**Time??**  $(d+1)b^0 + db^1 + (d-1)b^2 + \ldots + b^d = O(b^d)$ 

Space?? O(bd)

 $\underline{\text{Optimal??}} \text{ Yes, if step cost} = 1$ 

Can be modified to explore uniform-cost tree

Numerical comparison for b=10 and  $d=5\!\!$  , solution at far right leaf:

$$\begin{split} N(\mathsf{IDS}) &= 50 + 400 + 3,000 + 20,000 + 100,000 = 123,450 \\ N(\mathsf{BFS}) &= 10 + 100 + 1,000 + 10,000 + 100,000 + 999,990 = 1,111,100 \end{split}$$

 $\ensuremath{\mathsf{IDS}}$  does better because other nodes at depth d are not expanded

 $\ensuremath{\mathsf{BFS}}$  can be modified to apply goal test when a node is  $\ensuremath{\mathbf{generated}}$ 

© Shiart Russell Chapter 3 of AIMA 71

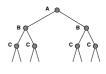

# Summary of algorithms

Criterion	Breadth-	Uniform-	Depth-	Depth-	Iterative
	First	Cost	First	Limited	Deepening
Complete?	Yes*	Yes*	No	Yes, if $l \geq d$	Yes
Time	$b^{d+1}$	$b^{\lceil C^*/\epsilon \rceil}$	$b^m$	$b^l$	$\mathcal{b}^{l}$
Space	$b^{d+1}$	$b^{\lceil C^*/\epsilon \rceil}$	bm	bl	bd
Optimal?	Yes*	Yes	No	No	Yes*

# Repeated states

Failure to detect repeated states can turn a linear problem into an exponential one!

#### Graph search

```
function GRAPH-SEARCH(problem, fringe) returns a solution, or failure closed ← an empty set fringe ← INSERT(MAKE-NODE(INITIAL-STATE[problem]), fringe) loop do

if fringe is empty then return failure

node ← REMOVE-FRONT(fringe)

if GOAL-TEST(problem, STATE[node]) then return node

if STATE[node] is not in closed then

add STATE[node] to closed

fringe ← INSERTALL(EXPAND(node, problem), fringe)

end
```

#### Partial summary

Problem formulation usually requires abstracting away real-world details to define a state space that can feasibly be explored  $\frac{1}{2} \left( \frac{1}{2} \right) = \frac{1}{2} \left( \frac{1}{2} \right) \left( \frac{1}{2$ 

Variety of uninformed search strategies

Iterative deepening search uses only linear space and not much more time than other uninformed algorithms

Graph search can be exponentially more efficient than tree search

© Smart Rared Capter 3 of ADMA 73 © Smart Rared Capter 3 of ADMA 74

### Informed Search Algorithms

- ♦ Best-first search
- $\Diamond$  A\* search
- ♦ Heuristics

# Best-first search

Idea: use an evaluation function for each node
- estimate of "desirability"

⇒ Expand most desirable unexpanded node

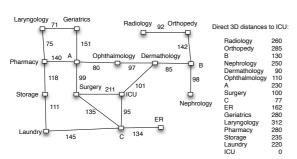

Implementation:

 $\ensuremath{\textit{fringe}}$  is a queue sorted in decreasing order of desirability

Special cases:

greedy search A\* search

# Blocket with distances in seconds

# Greedy search

$$\begin{split} & \text{Evaluation function } h(n) \text{ (heuristic)} \\ & = \text{estimate of cost from } n \text{ to the closest goal} \\ & \text{E.g., } h_{\text{SLD}}(n) = \text{straight-line distance from } n \text{ to ICU} \end{split}$$

Greedy search expands the node that appears to be closest to goal

A\* search

Idea: avoid expanding paths that are already expensive

Evaluation function f(n) = g(n) + h(n)

 $g(n) = \cos t$  so far to reach n

h(n) =estimated cost to goal from n

 $f(n) = {\it estimated total cost of path through } n {\it to goal}$ 

 $\mathsf{A}^*$  search uses an admissible heuristic

i.e.,  $h(n) \leq h^*(n)$  where  $h^*(n)$  is the true cost from n. (Also require  $h(n) \geq 0$ , so h(G) = 0 for any goal G.)

E.g.,  $h_{\rm SLD}(n)$  never overestimates the actual road distance

Theorem: A\* search is optimal

#### Optimality of A\* (standard proof)

Suppose some suboptimal goal  $G_2$  has been generated and is in the queue. Let n be an unexpanded node on a shortest path to an optimal goal  $G_1$ .

 $\begin{array}{ll} f(G_2) \,=\, g(G_2) & \text{ since } h(G_2) = 0 \\ > \, g(G_1) & \text{ since } G_2 \text{ is suboptimal} \\ \geq \, f(n) & \text{ since } h \text{ is admissible} \end{array}$ 

Since  $f(G_2) > f(n)$ ,  $A^*$  will never select  $G_2$  for expansion

Properties of A\*

# Properties of A\*

 $\underline{\text{Complete}??} \ \ \text{Yes, unless there are infinitely many nodes with} \ f \leq f(G)$ 

 $\underline{\text{Time}} \ref{time} \text{ Exponential in [relative error in } h \times \text{length of soln.]}$ 

Space?? Keeps all nodes in memory

Optimal  $\ref{fig:poisson}$  Yes—cannot expand  $f_{i+1}$  until  $f_i$  is finished

 $\mathsf{A}^*$  expands all nodes with  $f(n) < C^*$ 

 $\mathsf{A}^*$  expands some nodes with  $f(n) = C^*$ 

 $\mathsf{A}^*$  expands no nodes with  $f(n) > C^*$ 

#### Admissible heuristics

### E.g., for the 8-puzzle:

 $h_{\rm I}(n)=$  number of misplaced tiles  $h_2(n) = \text{total Manhattan distance}$ 

(i.e., no. of squares from desired location of each tile)

# Admissible heuristics

E.g., for the 8-puzzle:

 $h_1(n) = \text{number of misplaced tiles}$ 

 $h_2(n) = \text{total Manhattan distance}$ 

(i.e., no. of squares from desired location of each tile) 7 2 4 1 2 3 6 5 6 3 8

 $h_1(S) = ?? 6$  $\overline{h_2(S)}$  =?? 4+0+3+3+1+0+2+1 = 14

#### Dominance

If  $h_2(n) \ge h_1(n)$  for all n (both admissible) then  $h_2$  dominates  $h_1$  and is better for search

Typical search costs:

 $d = 14 \;\; \mathrm{IDS} = 3,473,941 \; \mathrm{nodes}$  $\begin{array}{c} \mathsf{A}^*(h_1)=539 \text{ nodes} \\ \mathsf{A}^*(h_2)=113 \text{ nodes} \\ d=24 \text{ IDS}\approx 54,000,000,000 \text{ nodes} \end{array}$  $A^*(h_1) = 39,135 \text{ nodes}$  $A^*(h_2) = 1,641$  nodes

Given any admissible heuristics  $h_a$ ,  $h_b$ ,

is also admissible and dominates  $h_a$ ,  $h_b$ 

 $h(n) = \max(h_a(n), h_b(n))$ 

# Relaxed problems

Admissible heuristics can be derived from the exact solution cost of a **relaxed** version of the problem

If the rules of the 8-puzzle are relaxed so that a tile can move anywhere, then  $h_1(n)$  gives the shortest solution

If the rules are relaxed so that a tile can move to any adjacent square, then  $h_2(n)$  gives the shortest solution

Key point: the optimal solution cost of a relaxed problem is no greater than the optimal solution cost of the real problem

Chapter 3 of AIMA 105 Chapter 3 of AIMA 106

# Summary

Heuristic functions estimate costs of shortest paths

Good heuristics can dramatically reduce search cost

Greedy best-first search expands lowest  $\hbar$ 

– incomplete and not always optimal

 $\mathsf{A}^*$  search expands lowest g+h

- complete and optimal

- also optimally efficient (up to tie-breaks, for forward search)

Admissible heuristics can be derived from exact solution of relaxed problems
