

Friday questions week 2

1. Consider an array `int a[10]` and a pointer `int* p`. After the statement:

```
p = &a[2];
```

What does `p + 2` mean?

page 59, 63, 72

2. Continued from previous question: what does `p[2]` mean?

page 59, 63, 72

3. If we also have `int* q = &a[5]`, what does `q - p` mean?

page 63

4. How can you allocate memory for a matrix of double elements when the number of rows and columns is unknown at compile-time and you wish to be able to use e.g. `a[i][j]` notation?

page 78

5. Continued from previous question: if you want to perform only one call to `malloc/calloc`, how can you then solve the problem?

page 77

6. Which potential risks are there with using `realloc`?

page 519

7. A macro can have parameters. Why is it a bad idea to define a macro `square` as:

```
square(a)    a*a
```
