

EDAF30 – Programming in C++

11. Low-level details. Loose ends.

Sven Gestegård Robertz
Computer Science, LTH

2023

Outline

1 Types

- Integer types

2 Saving space

- union
- Bit operations
- <bitset>

3 The comma operator

4 Templates

5 Tuples

6 Most vexing parse

7 C-strings – functions and warnings

- The C standard library string functions

Integer types

► Signed integers

Type	Size	Range (at least)
<code>signed char</code>	8 bits	$[-127, 127]^*$
<code>short</code>	at least 16 bits	$[-2^{15} + 1, 2^{15} - 1]$
<code>int</code>	at least 16 bits, usually 32	$[-2^{15} + 1, 2^{15} - 1]$
<code>long</code>	at least 32 bits	$[-2^{31} + 1, 2^{31} - 1]$
<code>long long</code>	at least 64 bits	$[-2^{63} + 1, 2^{63} - 1]$

*typically $[-128, 127]$, etc.

► Unsigned integers

- same size as corresponding `signed` type
- `unsigned char`: $[0, 255]$, `unsigned short`: $[0, 2^{16} - 1]$. etc.

► special case

- `char` (can be *represented* as `signed char` or `unsigned char`)
- Use `char` only for characters
- Use `signed char` or `unsigned char` for integer values

► Sizes according to the standard:

`char` \leq `short` \leq `int` \leq `long` \leq `long long`

Integer types

Overflow

- ▶ overflow of an **unsigned** n-bit integer is defined as
the value modulo 2^n
- ▶ overflow of a **signed** integer is *undefined (until C++-17)*

Integer types

Example with sizeof

```
#include <iostream>
using namespace std;
int main () {
    cout << "sizeof(char)= \t" << sizeof(char)<<endl;
    cout << "sizeof(short)= \t" << sizeof(short) <<endl;
    cout << "sizeof(int) = \t" << sizeof(int) <<endl;
    cout << "sizeof(long)= \t" << sizeof(long)<<endl;
}
sizeof(char)=    1
sizeof(short)=   2
sizeof(int) =    4
sizeof(long)=   8
```

Integer types

Sizes are specified in <climits>

CHAR_BIT	Number of bits in a char object (byte) (>=8)
SCHAR_MIN	Minimum value for an object of type signed char
SCHAR_MAX	Maximum value for an object of type signed char
UCHAR_MAX	Maximum value for an object of type unsigned char
CHAR_MIN	Minimum value for an object of type char (either SCHAR_MIN or 0)
CHAR_MAX	Maximum value for an object of type char (either SCHAR_MAX or UCHAR_MAX)
SHRT_MIN	Minimum value for an object of type short int
SHRT_MAX	Maximum value for an object of type short int
USHRT_MAX	Maximum value for an object of type unsigned short int
INT_MIN	Minimum value for an object of type int
INT_MAX	Maximum value for an object of type int
UINT_MAX	Maximum value for an object of type unsigned int
LONG_MIN	Minimum value for an object of type long int
LONG_MAX	Maximum value for an object of type long int
ULONG_MAX	Maximum value for an object of type unsigned long int
LLONG_MIN	Minimum value for an object of type long long int
LLONG_MAX	Maximum value for an object of type long long int
ULLONG_MAX	Maximum value for an object of type unsigned long long

Integer types

Sizes are specified in <climits>

```
#include <iostream>
#include <climits>
int main()
{
    std::cout << CHAR_MIN << ", " << CHAR_MAX << ", ";
    std::cout << UCHAR_MAX << std::endl;
    std::cout << SHRT_MIN << ", " << SHRT_MAX << ", ";
    std::cout << USHRT_MAX << std::endl;
    std::cout << INT_MIN << ", " << INT_MAX << ", ";
    std::cout << UINT_MAX << std::endl;
    std::cout << LONG_MIN << ", " << LONG_MAX << ", ";
    std::cout << ULONG_MAX << std::endl;
    std::cout << LLONG_MIN << ", " << LLONG_MAX << ", ";
    std::cout << ULLONG_MAX << std::endl;

}

128, 127, 255
-32768, 32767, 65535
-2147483648, 2147483647, 4294967295
-9223372036854775808, 9223372036854775807, 18446744073709551615
-9223372036854775808, 9223372036854775807, 18446744073709551615
```

Integer types

Sizes are implementation defined

Typedefs for specific sizes are in `<cstdint>` (`<stdint.h>`)

- ▶ integer types with exact width (if such a type exists):

```
int8_t int16_t int32_t int64_t
```

- ▶ fastest signed integer type with at least the width

```
int_fast8_t int_fast16_t int_fast32_t int_fast64_t
```

- ▶ smallest signed integer type with at least the width

```
int_least8_t int_least16_t int_least32_t int_least64_t
```

- ▶ signed integer type capable of holding a pointer:

```
intptr_t
```

- ▶ unsigned integer type capable of holding a pointer:

```
uintptr_t
```

The corresponding unsigned typedefs are named `uint_...._t`

union

The size of a normal **struct** (**class**) is *the sum* of its members

```
struct DataS {  
    int nr;  
    double v;  
    char txt[6];  
};
```

All members in a **struct** are laid out after each other in memory.

The size of a **union** is equal to *the size of the largest member*

```
union DataU {  
    int nr;  
    double v;  
    char txt[6];  
};
```

All members in a **union** have *the same address*: only one member can be used at any time.

union

Example use of DataU

```
union DataU {           DataU a;
    int nr;             a.nr = 57;
    double v;           cout << a.nr << endl;      57
    char txt[6];        a.v = 12.345;
};                      cout << a.v << endl;      12.345
                           strncpy(a.txt, "Tjo", 6);
                           cout << a.txt << endl;      Tjo
```

*The programmer is responsible for only using
the “right” member*

union

Example of wrong use

```
using std::cout;
using std::endl;

union Foo{
    int i;
    float f;
    double d;
    char c[10];
};

int main()
{
    Foo f;

    f.i = 12;
    cout << f.i << ", " << f.f << ", " << f.d << ", " << f.c << endl;

    strncpy(f.c, "Hej, du", 10);
    cout << f.i << ", " << f.f << ", " << f.d << ", " << f.c << endl;
}

12, 1.68156e-44, 5.92879e-323, ^L
745170248, 3.33096e-12, 1.90387e-306, Hej, du
```

union

encapsulate a union in a class to reduce the risk of mistakes

```
struct Bar{
    enum {undef, i, f, d, c} kind;
    Foo u;
};

void print(Bar b) {
    switch(b.kind){
        case Bar::i:
            cout << b.u.i << endl;
            break;
        case Bar::f:
            cout << b.u.f << endl;
            break;
        case Bar::d:
            cout << b.u.d << endl;
            break;
        case Bar::c:
            cout << b.u.c << endl;
            break;
        default:
            cout << "???" << endl;
            break;
    }
}
```

```
void test_kind()
{
    Bar b{};
    b.kind = Bar::i;
    b.u.i = 17;

    print(b);

    Bar b2{};
    print(b2);
}

17
???
```

union

anonymous **union** – removes one level

An alternative to the previous example:

```
struct FooS{
    enum {undef, k_i, k_f, k_d, k_c} kind;
    union{
        int i;
        float f;
        double d;
        char c[10];
    };
};

FooS test;
```

```
test.kind = FooS::k_c;
strncpy(test.c, "Testing", 10);
if(test.kind == FooS::k_c)
    cout << test.c << endl;
```

Testing

*Exposing the tag to the users
is brittle.*

Tagged `union`

A class with anonymous `union` and access functions

```
struct FooS{
    enum {undef, k_i, k_f, k_d, k_c} kind;
    union{
        int i;
        float f;
        double d;
        char c[10];
    };
    FooS()           :kind{undef} {}
    FooS(int ii)    :kind{k_i},i{ii} {}
    FooS(float fi)  :kind{k_f},f{fi} {}
    FooS(double di) :kind{k_d},d{di} {}
    FooS(const char* ci) :kind{k_c} {strncpy(c,ci,10);}
    int     get_i() {assert(kind==k_i); return i;}
    float   get_f() {assert(kind==k_f); return f;}
    double  get_d() {assert(kind==k_d); return d;}
    char*   get_c() {assert(kind==k_c); return c;}
    FooS& operator=(int ii) {kind=k_i; i = ii; return *this;}
    FooS& operator=(float fi) {kind=k_f; f = fi; return *this;}
    FooS& operator=(double di) {kind=k_d; d = di; return *this;}
    FooS& operator=(const char* ci){kind=k_c; strncpy(c,ci,10);
                                    return *this;}
};
```

Bitwise operators

Bitwise and: `a & b`

shift left: `a << 5`

Bitwise or: `a | b`

shift right: `a >> 5`

Bitwise xor: `a ^ b`

*>> on signed types is
implementation defined*

Bitwise complement: `~a`

Common operations:

set 5th bit

```
a = a | (1 << 4);  
a |= (1 << 4);
```

clear 5th bit

```
a = a & ~(1 << 4);  
a &= ~(1 << 4);
```

toggle 5th bit

```
a = a ^ (1 << 4);  
a ^= (1 << 4);
```

Bitwise operators

Example:

Low-level operations: Bitwise operators

All variables are unsigned 16 bit integers

```
a = 77;           // a = 0000 0000 0100 1101
b = 22;           // b = 0000 0000 0001 0110
c = ~a;           // c = 1111 1111 1011 0010
d = a & b;         // d = 0000 0000 0000 0100
e = a | b;         // e = 0000 0000 0101 1111
f = a ^ b;         // f = 0000 0000 0101 1011
g = a << 3;        // g = 0000 0010 0110 1000
h = c >> 5;        // h = 0000 0111 1111 1101
i = a & 0x000f;      // i = 0000 0000 0000 1101
j = a | 0xf000;      // j = 1111 0000 0100 1101
k = a ^ (1 << 4);    // k = 0000 0000 0101 1101
```

`std::bitset (<bitset>)`

- ▶ efficient class for storing a set of bits
 - ▶ compact
 - ▶ fast
- ▶ has convenient functions
 - ▶ test, **operator[]**
 - ▶ set, reset, flip
 - ▶ any, all, none, count
 - ▶ conversion to/from string
 - ▶ I/O operators
- ▶ cf. `std::vector<bool>`
 - ▶ `std::bitset` has fixed size
 - ▶ a `std::vector` can grow
 - ▶ but does not quite behave like a normal `std::vector<T>`

bitset

Example: store 50 flags in 8 bytes

```
void test_bitop(){
    bool status;
    cout << std::boolalpha;

    unsigned long quizA = 0;

    quizA |= 1UL << 27 ;
    status = quizA & (1UL << 27);
    cout << "student 27: " ;
    cout << status << endl;

    quizA &= ~(1UL << 27);
    status = quizA & (1UL << 27);
    cout << "student 27: ";
    cout << status << endl;
}

student 27: true
student 27: false
```

```
void test_bitset(){
    bool status;
    cout << std::boolalpha;

    std::bitset<50> quizB;

    quizB.set(27);
    status = quizB[27];
    cout << "student 27: " ;
    cout << status << endl;

    quizB.reset(27);
    status = quizB[27];
    cout << "student 27: ";
    cout << status << endl;
}

student 27: true
student 27: false
```

The comma operator (Introduction and warning)

The comma operator expression expression1, expression2

- ▶ First evaluates expression1, then expression2
- ▶ the expression has the value of expression2
- ▶ NB! The comma separating function parameters or arguments is *not* the comma operator
- ▶ Examples:

```
string s;
while(cin >> s, s.length() > 5) {  
    //do something  
}  
  
std::vector<int> v(10);  
  
vector<int>::size_type cnt = v.size();  
for(vector<int>::size_type i=0; i < v.size(); ++i, --cnt) {  
    v[i]=cnt;  
} v now contains 10 9 8 7 6 5 4 3 2 1
```

*This ignores the value of cin >> s
use && instead of ,*

Do not use the comma operator!

Template metaprogramming

- ▶ Write code that is executed *by the compiler, at compile-time*
- ▶ Common in the standard library
 - ▶ As optimization: move computations from run-time to compile-time
 - ▶ As utilities: e.g., `type_traits`, `iterator_traits`
- ▶ Metafunction: a class template containing the result
- ▶ Standard library conventions:
 - ▶ Type results: type member named `type`
 - ▶ Value results: value member named `value`

Template metaprogramming

Example of compile-time computation

```
template <int N>
struct Factorial{
    static constexpr int value = N * Factorial<N-1>::value;
};

template <>
struct Factorial<0>{
    static constexpr int value = 1;
};

void example()
{
    Show<int, Factorial<5>::value>{};
}
```

Result of the *meta-function call* as a compiler error:

```
error: invalid use of incomplete type 'struct Show<int, 120>'
      Show< int, Factorial<5>::value >{};
```

Template metaprogramming

Example of templates for getting values as compiler errors

- ▶ Trick: use a template that doesn't compile to get information about the template parameters through a compiler error.
- ▶ Can be useful for debugging templates.
- ▶ To get the type parameter T:

```
template <typename T>
struct ShowType;
```

- ▶ To get a value (N) of type T:

```
template <typename T, T N>
struct Show;
```

std::tuple
less than for a Person class

```
#include <tuple>

struct Person
{
    std::string fname;
    std::string lname;

    /* Order Persons by lname, fname */
    bool operator<(const Person& p) const {
        return std::tie(lname, fname) < std::tie(p.lname, p.fname);
    }
};
```

Tuple has an operator<.

std::tuple
get of type

```
auto t = std::make_tuple<17, 42.1, "Hello">;  
  
auto i = std::get<int>(t);  
auto d = std::get<double>(t);
```

Most vexing parse

Example 1

```
struct Foo {  
    int x;  
};  
  
int main()  
{  
#ifdef ERROR1  
    Foo f(); // function declaration  
#else  
    Foo f{}; // Variable declaration C++11  
    // Foo f; //C++98 (but not initialized)  
#endif  
    cout << f.x << endl; // Error  
  
    Foo g = Foo(); // OK      // C++11: auto g = Foo();  
    cout << g.x << endl;  
  
error: request for member 'x' in 'f', which is of  
non-class type 'Foo()'
```

Most vexing parse

Example 2

```
struct Foo {
    int x;
};

struct Bar {
    int x;
    Bar(Foo f) :x{f.x} {}
};

int main()
{
#define ERROR2
    Bar b(Foo()); // function declaration
#else
    Bar b{Foo()}; // Variable declaration (C++11)
    // Bar b((Foo())); // C++98 : extra parentheses --> expression
#endif
    cout << b.x << endl; // Error!

error: request for member 'x' in 'b', which is of
non-class type 'Bar(Foo (*)())'
```

Most vexing parse

Example: actual function

```
struct Foo {  
    Foo(int i=0) :x{i} {}  
    int x;  
};  
  
struct Bar {  
    int x;  
    Bar(Foo f) :x{f.x} {}  
};  
  
Bar b(Foo()); // forward declaration
```

```
Foo make_foo()  
{  
    return Foo(17);  
}
```

```
Bar b(Foo(*f)())  
{  
    return Bar(f());  
}
```

```
void test()  
{  
    Bar tmp = b(make_foo());  
    cout << tmp.x << endl;  
}
```

17

C-strings – library functions

functions in <cstring>

```
strcpy(dest,src)      // Copies src to dest
strncpy(dest,src,n)   // Copies at most n chars
NB! dest is not null-terminated when truncating

strcat(s,t)           // Appends a copy of t to the end of s
strncat(s,t,n)        // Appends at most n chars

strlen(s)              // Gives the length of s
strlen(s,n)            // Gives the length of s, max n chars

strcmp(s,t)            // Compare s and t
strncmp(s,t,n)         // ... at most n chars
// s<t, s==t, s>t returns <0, =0, >0 respectively
```

(even more) unsafe, avoid when possible!

String input

Example mistake

The read string does not fit in x

The statements

```
char z[] {"zzzz"};
char y[] {"yyyy"};
char x[5];

stringstream sin{"aaaaaaaaaaaaaaaaaa bbbbbbb"};
sin >> x;

cout << x << " : " << y << " : " << z << endl;
```

Give the output (on my computer):

aaaaaaaaaaaaaaaaaa : **aa** : zzzz

- ▶ C-strings don't do bounds checking
- ▶ the input to x has overwritten (part of) y
- ▶ `getline()` is safer

Copying strings

Failing example

The statements

```
char s[20];  
  
strncpy(s, "abc", 4);  
cout << s << endl;  
  
strncpy(s, "kalle anka", 20);  
cout << s << endl;  
  
strncpy(s, "def", 3);  
cout << s << endl;
```

produce the output

```
abc  
kalle anka  
defle anka
```

The statements

```
int data[] {558646598, 65, 66};  
char x[16];  
char t[30] {"test"};  
  
strncpy(x, "abcdefghijklmноп", 16);  
strcpy(t,x);  
cout << t << endl;
```

produce the output

```
abcdefghijklмнопFEL!A
```

Note

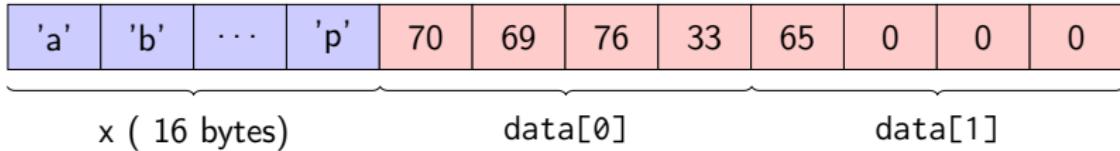

- `strncpy` does not terminate the string with a `\0` when truncating.
- `strcpy` copies until it finds a `\0` in src.

Copying strings

Failing example: explanation

```
int data[] { 558646598, 65, 66};  
char x[16];
```

- ▶ the bytes of `data` is interpreted as `char`.
- ▶ representation in memory

Hexadecimal representation:

$$558646598_{10} = 214c4546_{16}$$

$$65_{10} = 41_{16}$$

Byte order: *little-endian*

hex	ASCII)	dec
46	F	70
45	E	69
4c	L	76
21	!	33
41	A	65
0	\0	0
0	\0	0
0	\0	0
...
