# PROBLEM SOLVING AND SEARCH BY STUART RUSSELL

# MODIFIED BY JACEK MALEC FOR LTH LECTURES JANUARY 19TH, 2018

CHAPTER 3 OF AIMA

Stuart Russell

Chapter 3 of AIMA 1

# Problem-solving agents

Restricted form of general agent:

```
function SIMPLE-PROBLEM-SOLVING-AGENT (percept) returns an action static: seq, an action sequence, initially empty state, some description of the current world state goal, a goal, initially null problem, a problem formulation state \leftarrow \text{UPDATE-STATE}(state, percept) if seq is empty then goal \leftarrow \text{FORMULATE-GOAL}(state) problem \leftarrow \text{FORMULATE-PROBLEM}(state, goal) seq \leftarrow \text{SEARCH}(problem) action \leftarrow \text{RECOMMENDATION}(seq, state) seq \leftarrow \text{REMAINDER}(seq, state) return action
```

Note: this is offline problem solving; solution executed "eyes closed." Online problem solving involves acting without complete knowledge.

#### Outline

- ♦ Problem-solving agents
- ♦ Problem types
- ♦ Problem formulation
- ♦ Example problems
- ♦ Basic (uninformed) search algorithms
- ♦ Informed search algorithms

© Stuart Russell Chapter 3 of AIMA 2

# Example: Blocket

© Jorchr / Wikimedia Commons / CC-BY-SA-3.0 / GFDL

© Stuart Russell Chapter 3 of AIMA 3 © Stuart Russell Chapter 3 of AIMA 4

#### Example: Blocket

Service robot Odin, delivering drugs to divisions. Currently in the Pharmacy. There is a drug order from Intensive Care Unit.

Formulate goal:

be in Intensive Care Unit

Formulate problem:

states: various locations

actions: drive between locations

Find solution:

sequence of locations, e.g., Pharmacy, Elevator A, Surgery, ICU

# Problem types

Deterministic, fully observable ⇒ single-state problem

Agent knows exactly which state it will be in; solution is a sequence

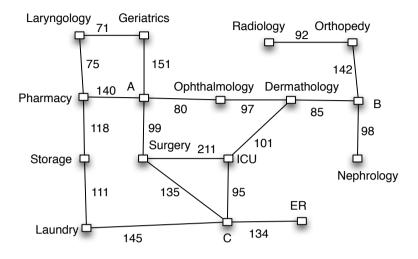

Non-observable ⇒ conformant problem

Agent may have no idea where it is; solution (if any) is a sequence

Nondeterministic and/or partially observable  $\implies$  contingency problem percepts provide **new** information about current state solution is a contingent plan or a policy often **interleave** search, execution

Unknown state space ⇒ exploration problem ("online")

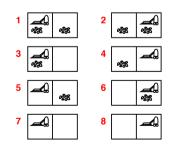

#### Example: Blocket

Stuart Russell Chapter 3 of AIMA 6

# Example: vacuum world

Single-state, start in #5. Solution??

Chapter 3 of AIMA 7 © Stuart Russell Chapter 3 of AIMA 8

#### Example: vacuum world

Single-state, start in #5. Solution?? [Right, Suck]

Conformant, start in  $\{1, 2, 3, 4, 5, 6, 7, 8\}$ e.g., Right goes to  $\{2, 4, 6, 8\}$ . Solution??

© Stuart Russell

# Example: vacuum world

Single-state, start in #5. Solution?? [Right, Suck]

Conformant, start in  $\{1, 2, 3, 4, 5, 6, 7, 8\}$ e.g., Right goes to  $\{2,4,6,8\}$ . Solution?? [Right, Suck, Left, Suck]

Contingency, start in #5

Murphy's Law: Suck can dirty a clean carpet Local sensing: dirt, location only.

Solution??

[Right, if dirt then Suck]

Chapter 3 of AIMA 9

#### Example: vacuum world

Single-state, start in #5. Solution?? [Right, Suck]Conformant, start in  $\{1, 2, 3, 4, 5, 6, 7, 8\}$ e.g., Right goes to  $\{2,4,6,8\}$ . Solution???

[Right, Suck, Left, Suck]Contingency, start in #5

Murphy's Law: Suck can dirty a clean carpet

Solution??

Local sensing: dirt, location only.

© Stuart Russell Chapter 3 of AIMA 10

# Single-state problem formulation

A problem is defined by four items:

```
initial state e.g., "at Pharmacy"
successor function S(x) = \text{set of action-state pairs}
       e.g., S(Pharmacy) = \{\langle Pharmacy \rightarrow Storage, Storage \rangle, \ldots \}
goal test, can be
       explicit, e.g., x = "at ICU"
       implicit, e.g., NoDirt(x)
path cost (additive)
        e.g., sum of distances, number of actions executed, etc.
```

A solution is a sequence of actions leading from the initial state to a goal state

c(x, a, y) is the step cost, assumed to be > 0

#### Selecting a state space

Real world is absurdly complex

 $\Rightarrow$  state space must be **abstracted** for problem solving

(Abstract) state = set of real states

(Abstract) action = complex combination of real actions e.g., "Pharmacy  $\rightarrow$  Storage" represents a complex set of possible routes, detours, rest stops, etc.

For guaranteed realizability, **any** real state "in Pharmacy" must get to some real state "in Storage"

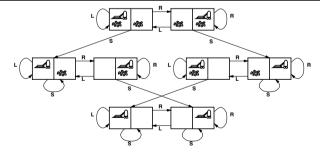

(Abstract) solution =

set of real paths that are solutions in the real world

Each abstract action should be "easier" than the original problem!

Chapter 3 of AIMA 21

# Example: The 8-puzzle

Start State

Goal State

states??: integer locations of tiles (ignore intermediate positions)
actions??: move blank left, right, up, down (ignore unjamming etc.)
goal test??: = goal state (given)
path cost??: 1 per move

[Note: optimal solution of  $n ext{-}\text{Puzzle family is NP-hard}]$ 

#### Example: The 8-puzzle

Start State

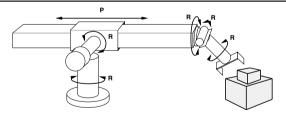

**Goal State** 

states??: integer locations of tiles (ignore intermediate positions)
actions??: move blank left, right, up, down (ignore unjamming etc.)
goal test??: = goal state (given)
path cost??

© Stuart Russell

Chapter 3 of AIMA 22

#### Example: robotic assembly

states??: real-valued coordinates of robot joint angles
 parts of the object to be assembled

actions??: continuous motions of robot joints

goal test??: complete assembly with no robot included!

path cost??: time to execute

# Tree search algorithms

#### Basic idea:

offline, simulated exploration of state space by generating successors of already-explored states (a.k.a. expanding states)

 $\begin{tabular}{ll} \bf function & \bf Tree-Search (\it problem, strategy) & \bf returns & \bf a solution, or failure \\ & initialize & the search & tree & using the initial state of & problem \\ & \bf loop & \bf do & \\ \end{tabular}$ 

if there are no candidates for expansion **then return** failure choose a leaf node for expansion according to strategy if the node contains a goal state **then return** the corresponding solution **else** expand the node and add the resulting nodes to the search tree

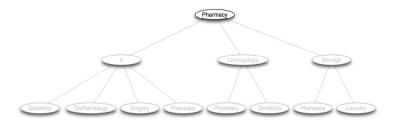

end

Stuart Russell Chapter 3 of AIMA 25

# Tree search example

#### Tree search example

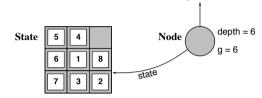

tuart Russell Chapter 3 of AIMA 26

# Tree search example

#### Implementation: states vs. nodes

A state is a (representation of) a physical configuration A node is a data structure constituting part of a search tree includes parent, children, depth, path cost g(x) States do not have parents, children, depth, or path cost!

The EXPAND function creates new nodes, filling in the various fields and using the SUCCESSORFN of the problem to create the corresponding states.

© Stuart Russell Chapter 3 of AIMA 29

#### Search strategies

A strategy is defined by picking the order of node expansion

Strategies are evaluated along the following dimensions:

completeness—does it always find a solution if one exists? time complexity—number of nodes generated/expanded space complexity—maximum number of nodes in memory optimality—does it always find a least-cost solution?

Time and space complexity are measured in terms of

b—maximum branching factor of the search tree

d—depth of the least-cost solution

m—maximum depth of the state space (may be  $\infty$ )

#### Implementation: general tree search

```
function TREE-SEARCH(problem, fringe) returns a solution, or failure
   fringe \leftarrow Insert(Make-Node(Initial-State[problem]), fringe)
  loop do
        if fringe is empty then return failure
        node \leftarrow Remove-Front(fringe)
        if GOAL-TEST(problem.STATE(node)) then return node
        fringe \leftarrow InsertAll(Expand(node, problem), fringe)
function EXPAND( node, problem) returns a set of nodes
   successors \leftarrow the empty set
   for each action, result in Successor-Fn(problem, State[node]) do
        s \leftarrow a \text{ new Node}
        PARENT-NODE[s] \leftarrow node; ACTION[s] \leftarrow action; STATE[s] \leftarrow result
       PATH-COST[s] \leftarrow PATH-COST[node] + STEP-COST(STATE[node], action,
        Depth[s] \leftarrow Depth[node] + 1
        add s to successors
   return successors
```

© Stuart Russell Chapter 3 of AIMA 30

# Uninformed search strategies

Uninformed strategies use only the information available in the problem definition

Sometimes called **blind** search strategies

Breadth-first search

Uniform-cost search

Depth-first search

Depth-limited search

Iterative deepening search

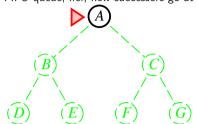

© Stuart Russell Chapter 3 of AIMA 31 © Stuart Russell Chapter 3 of AIMA 32

#### Breadth-first search

Expand shallowest unexpanded node

#### Implementation:

fringe is a FIFO queue, i.e., new successors go at end

## Properties of breadth-first search

Complete??

Stuart Russell

# Properties of breadth-first search

 $\underline{\mathsf{Complete}} \ensuremath{\mathbf{??}} \ensuremath{\mathsf{Yes}} \ensuremath{\mathsf{(if}} \ensuremath{b} \ensuremath{\mathsf{is}} \ensuremath{\mathsf{finite}} \ensuremath{\mathsf{)}}$ 

$$\underline{\text{Time}} \ref{Time} ?\ref{Time} 1 + b + b^2 + b^3 + \ldots + b^d + b(b^d - 1) = O(b^{d+1}) \text{, i.e., exp. in } d$$
 Space??

# Properties of breadth-first search

Complete?? Yes (if b is finite)

Time??

© Stuart Russell Chapter 3 of AIMA 38

# Properties of breadth-first search

 $\underline{\mathsf{Complete}} \ensuremath{\mathbf{??}} \ensuremath{\mathsf{Yes}} \ensuremath{\mathsf{(if}} \ensuremath{b} \ensuremath{\mathsf{is}} \ensuremath{\mathsf{finite}} \ensuremath{\mathsf{)}}$ 

Time??  $1 + b + b^2 + b^3 + \ldots + b^d + b(b^d - 1) = O(b^{d+1})$ , i.e., exp. in d

Chapter 3 of AIMA 40

 $\underline{\text{Space}} \ref{Space} \ O(b^{d+1}) \ \text{(keeps every node in memory)}$ 

Optimal??

Chapter 3 of AIMA 37

# Properties of breadth-first search

Complete?? Yes (if b is finite)

<u>Time</u>??  $1 + b + b^2 + b^3 + \ldots + b^d + b(b^d - 1) = O(b^{d+1})$ , i.e., exp. in d

Space??  $O(b^{d+1})$  (keeps every node in memory)

Optimal?? Yes (if cost = 1 per step); not optimal in general

**Space** is the big problem; can easily generate nodes at 100MB/sec so 24hrs = 8640GB.

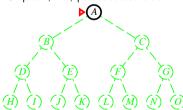

© Stuart Russell Chapter 3 of AIMA 41

# Depth-first search

Expand deepest unexpanded node

#### Implementation:

fringe = LIFO queue, i.e., put successors at front

#### Uniform-cost search

Expand least-cost unexpanded node

#### Implementation:

 $\mathit{fringe} = \mathsf{queue}$  ordered by path cost, lowest first

Equivalent to breadth-first if step costs all equal

Complete?? Yes, if step cost  $\geq \epsilon$ 

 $\underline{\operatorname{Time}} \ref{thm:property} \ \# \ \text{of nodes with} \ g \leq \ \operatorname{cost} \ \text{of optimal solution}, \ O(b^{\lceil C^*/\epsilon \rceil})$  where  $C^*$  is the cost of the optimal solution

Space?? # of nodes with  $g \leq \cos$  of optimal solution,  $O(b^{\lceil C^*/\epsilon \rceil})$ 

Optimal?? Yes—nodes expanded in increasing order of g(n)

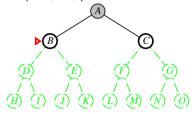

Stuart Russell Chapter 3 of AIMA 42

# Summary of algorithms

Criterion	Breadth- First	Uniform- Cost	Depth- First	Depth- Limited	Iterative Deepening
Complete?	$Yes^* \\ b^{d+1}$	$Yes^* \\ b^{\lceil C^*/\epsilon \rceil}$	No $b^m$	$ \text{Yes, if } l \geq d \\ b^l $	${\displaystyle \mathop{Yes}_{b^d}}$
Space Optimal?	$b^{d+1}$ Yes $^*$	$b^{\lceil C^*/\epsilon ceil}$ Yes	bm	<i>bl</i> No	$bd$ Yes $^{st}$

#### Properties of iterative deepening search

Complete?? Yes

Time?? 
$$(d+1)b^0 + db^1 + (d-1)b^2 + \ldots + b^d = O(b^d)$$

Space?? O(bd)

Optimal?? Yes, if step cost = 1

Can be modified to explore uniform-cost tree

Numerical comparison for b=10 and d=5, solution at far right leaf:

$$N(\mathsf{IDS}) = 50 + 400 + 3,000 + 20,000 + 100,000 = 123,450$$
  
 $N(\mathsf{BFS}) = 10 + 100 + 1,000 + 10,000 + 100,000 + 999,990 = 1,111,100$ 

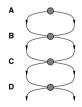

IDS does better because other nodes at depth  $\emph{d}$  are not expanded

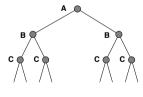

BFS can be modified to apply goal test when a node is generated

Stuart Russell Chapter 3 of AIMA 70

# Repeated states

Failure to detect repeated states can turn a linear problem into an exponential one!

#### Graph search

```
function GRAPH-SEARCH(problem, fringe) returns a solution, or failure
  closed \leftarrow an empty set
  fringe \leftarrow Insert(Make-Node(Initial-State[problem]), fringe)
  loop do
       if fringe is empty then return failure
       node \leftarrow Remove-Front(fringe)
       if GOAL-TEST(problem, STATE[node]) then return node
       if STATE[node] is not in closed then
           add STATE[node] to closed
           fringe \leftarrow InsertAll(Expand(node, problem), fringe)
  end
```

© Stuart Russell Chapter 3 of AIMA 73

# Informed Search Algorithms

- ♦ Best-first search
- $\Diamond$  A\* search
- ♦ Heuristics

#### Partial summary

Problem formulation usually requires abstracting away real-world details to define a state space that can feasibly be explored

Variety of uninformed search strategies

Iterative deepening search uses only linear space and not much more time than other uninformed algorithms

Graph search can be exponentially more efficient than tree search

© Stuart Russell Chapter 3 of AIMA 74

#### Best-first search

Idea: use an evaluation function for each node

- estimate of "desirability"

⇒ Expand most desirable unexpanded node

Implementation:

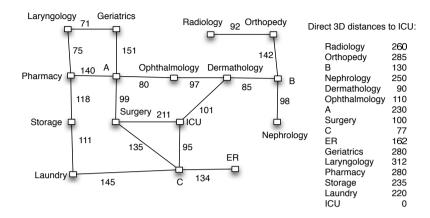

fringe is a queue sorted in decreasing order of desirability

Special cases:

greedy search A\* search

Chapter 3 of AIMA 75 Chapter 3 of AIMA 76

## Blocket with distances in seconds

#### A\* search

Idea: avoid expanding paths that are already expensive

Evaluation function f(n) = g(n) + h(n)

 $g(n) = \cos t$  so far to reach n

h(n) =estimated cost to goal from n

f(n) =estimated total cost of path through n to goal

A\* search uses an admissible heuristic

i.e.,  $h(n) \leq h^*(n)$  where  $h^*(n)$  is the  ${\bf true}$  cost from n.

(Also require  $h(n) \ge 0$ , so h(G) = 0 for any goal G.)

E.g.,  $h_{\rm SLD}(n)$  never overestimates the actual road distance

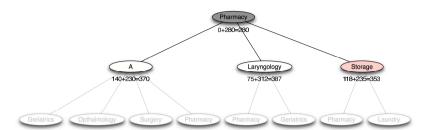

Theorem: A\* search is optimal

## Optimality of A\* (standard proof)

Suppose some suboptimal goal  $G_2$  has been generated and is in the queue. Let n be an unexpanded node on a shortest path to an optimal goal  $G_1$ .

$$f(G_2) = g(G_2)$$
 since  $h(G_2) = 0$   
>  $g(G_1)$  since  $G_2$  is suboptimal  
 $\geq f(n)$  since  $h$  is admissible

Since  $f(G_2) > f(n)$ , A\* will never select  $G_2$  for expansion

© Stuart Russell Chapter 3 of AIMA 97

# Properties of A\*

Complete?? Yes, unless there are infinitely many nodes with  $f \leq f(G)$ 

Time??

# Properties of A\*

#### Dominance

```
If h_2(n) \ge h_1(n) for all n (both admissible) then h_2 dominates h_1 and is better for search
```

Typical search costs:

$$\begin{array}{ll} d=14 & {\rm IDS}=3,473,941 \ {\rm nodes} \\ & {\rm A}^*(h_1)=539 \ {\rm nodes} \\ & {\rm A}^*(h_2)=113 \ {\rm nodes} \\ d=24 & {\rm IDS}\approx 54,000,000,000 \ {\rm nodes} \\ & {\rm A}^*(h_1)=39,135 \ {\rm nodes} \\ & {\rm A}^*(h_2)=1,641 \ {\rm nodes} \end{array}$$

Given any admissible heuristics  $h_a$ ,  $h_b$ ,

$$h(n) = \max(h_a(n), h_b(n))$$

is also admissible and dominates  $h_a$ ,  $h_b$

# Summary

Heuristic functions estimate costs of shortest paths

Good heuristics can dramatically reduce search cost

Greedy best-first search expands lowest  $\boldsymbol{h}$ 

- incomplete and not always optimal

 $A^*$  search expands lowest q + h

- complete and optimal
- also optimally efficient (up to tie-breaks, for forward search)

Admissible heuristics can be derived from exact solution of relaxed problems

© Stuart Russell Chapter 3 of AIMA 107

#### Relaxed problems

Admissible heuristics can be derived from the **exact** solution cost of a **relaxed** version of the problem

If the rules of the 8-puzzle are relaxed so that a tile can move anywhere, then  $h_1(n)$  gives the shortest solution

If the rules are relaxed so that a tile can move to any adjacent square, then  $h_2(n)$  gives the shortest solution

Key point: the optimal solution cost of a relaxed problem is no greater than the optimal solution cost of the real problem
