Choosing Project

- EDAP01, Artificial Intelligence
- AlphaGo Zero paper
- Chess requires strong hardware

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

AlphaGo Zero

- Previous method used supervised learning
- Zero learns tabula rasa
- Policy network outputs action probability vector
- Value network estimates expected reward for state s

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

AlphaGo Zero

- MCTS executed for each position
- Selects moves that maximize $Q(s, a) + \frac{P(s,a)}{(1+N(s,a))}$
- Edges traversed in search update visit count, and action value
- ▶ Visit count *N*(*s*, *a*) becomes target search probabilities
- data (s, π, z), minimize error of predicted value and winner, maximize similarity to π

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Differences to previous AlphaGo

No supervised learning from human data

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

- No rollouts
- Only boards as input

My version

- Started by pretraining policy and value network
- Test agains randomp player and filterplayer
- Then reinforcement learning with MCTS
- Leaf evaluation using rollouts + value network
- Rollout uses fast policy + randomness, relied more on rollouts in beginning

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Update data for all timesteps after termination

- End nodes have value z
- ▶ Other nodes have value $\frac{1}{N(s_{t-1},a_{t-1})}\sum_b N(s_t,b_t) \cdot Q(s_t,b_t)$

Probabilities is visit percentage per edge

Some features

- Leaf node lambda depends on number of available moves at s' and depth of rollout
- Value updates for edges also depend on depth at obtained result
- Node satisfaction
 - if child C is terminal then parent node is satisfied
 - if there exists a satisfied child node with value 1 (win), parent node is also satisfied

- if all children are satisfied parent is also satisfied
- Parent value = -max(childvalue)
- Used this to update data after game is finished

Reflections

- Can we tell if search probabilities are wrong?
 - When edges are satisfied "bad moves" can't be seen as bad if loss is inevitable

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

- if not satisfied, maybe loss could be avoided
- When values are updated we're essentially updating probability of win in state s
- If new win probability is lower than previously thought, the difference could be seen as new observations
