

Exercise- Partially applied functions and Special function call forms

You own a bookstore at Mårtenstorget. For each book you sell you have to pay tax (moms) that adds 6% to the price.

You are given a function that calculates the tax:

```
def taxCalculator(cost: Double, percent: Double) =  
{cost*percent/(100+percent)}
```

Now, write a method `receipt` that takes a function for your tax calculation and an arbitrary number of tuples with the book information (e.g title and author) and the book cost and for each book, prints the title, price and tax.

Output example:

Welcome to Maj book store

Items bought:

Programming in Scala by Martin Odersky, price 366 kr (moms 20.72 kr).

Thank you and have a nice day!
