Preface

The roots of the Power ISA (Instruction Set Architecture) extend back over a quarter of a century, to IBM Research. The POWER (Performance Optimization With Enhanced RISC) Architecture was introduced with the RISC System/6000 product family in early 1990. In 1991, Apple, IBM, and Motorola began the collaboration to evolve to the PowerPC Architecture, expanding the architecture's applicability. In 1997, Motorola and IBM began another collaboration, focused on optimizing PowerPC for embedded systems, which produced Book E.

In 2006, Freescale and IBM collaborated on the creation of the Power ISA Version 2.03, which represented the reunification of the architecture by combining Book E content with the more general purpose PowerPC Version 2.02. A significant benefit of the reunification is the establishment of a single, compatible, 64-bit programming model. The combining also extends explicit architectural endorsement and control to Auxiliary Processing Units (APUs), units of function that were originally developed as implementation- or product family-specific extensions in the context of the Book E allocated opcode space. With the resulting architectural superset comes a framework that clearly establishes requirements and identifies options.

To a very large extent, application program compatibility has been maintained throughout the history of the architecture, with the main exception being application exploitation of APUs. The framework identifies the base, pervasive, part of the architecture, and differentiates it from “categories” of optional function (see Section 1.3.5 of Book I). Because of the substantial differences in the supervisor (privileged) architecture that developed as Book E was optimized for embedded systems, the supervisor architectures for embedded and general purpose implementations are represented as mutually exclusive categories. Future versions of the architecture will seek to converge on a common solution where possible.

This document defines the Power ISA Version 2.07. It is comprised of five books and a set of appendices.

Book I, Power ISA User Instruction Set Architecture, covers the base instruction set and related facilities available to the application programmer. It includes five chapters derived from APU function, including the vector extension also known as Altivec.

Book II, Power ISA Virtual Environment Architecture, defines the storage model and related instructions and facilities available to the application programmer.

Book III-S, Power ISA Operating Environment Architecture, defines the supervisor instructions and related facilities used for general purpose implementations.

Book III-E, Power ISA Operating Environment Architecture, defines the supervisor instructions and related facilities used for embedded implementations. It was derived from Book E and extended to include APU function.

Book VLE, Power ISA Variable Length Encoded Instructions Architecture, defines alternative instruction encodings and definitions intended to increase instruction density for very low end implementations. It was derived from an APU description developed by Freescale Semiconductor.

As used in this document, the term “Power ISA” refers to the instructions and facilities described in Books I, II, III-S, III-E, and VLE.

Usage of the phrase “Book III” refers to both Book III-S and Book III-E. An exception to this rule is when, at the beginning of a Section or Book, it is specified that usage of the phrase “Book III” implies only either “Book III-S” or “Book III-E”.

Change bars have been included to indicate changes from the Power ISA Version 2.06B.
Summary of Changes in Power ISA Version 2.07

Version 2.07 of the PowerISA was created by applying the following requests for change (RFCs) to PowerISA Version 2.06B.

Performance Monitor Facility: Adds various performance monitoring facilities and a branch history buffer to Server architecture.

VSX Scalar Single-Precision: Adds support for scalar single-precision to VSX.

Transactional Memory: Adds support for a transactional memory storage model which allows an application to perform a sequence of accesses that appear to occur atomically with respect to other threads.

Processor Control Enhancements: Enables privileged and hypervisor software to send messages to other threads.

Instruction Cache Block Touch: The icbt instruction has been moved from the Embedded category to the Base category.

Extended Problem State Priority: Provides a mechanism that enables application programs to temporarily boost their priority.

Virtual Page Class Key Extensions for Instructions: Adds a new SPR similar to the AMR that controls whether instructions can be fetched from virtual addresses.

Reserved Bit Behavior Restriction and Processor Compatibility Register: Updates the PCR to accommodate new problem state features for PowerISA Version 2.07. In addition, requirements for reserved bit behaviors have been tightened in order to improve software compatibility across implementations.

Chip Information Register: Adds a privileged SPR which enables software to determine information about the chip on which the processor is implemented.

Crypto Operations: Adds instructions supporting AES, GCM, and SHA encryption and decryption, as well as a variety of CRCs and other finite field arithmetic operations.

VMX 64-Bit Integer Operations: Adds instructions supporting 2-way SIMD 64-bit integer operations.

Vector Miscellaneous Instructions: Adds SIMD count leading zeros instructions and a bit gather instruction.

Cache Hint Indicating Block Not Needed: Enables software to provide a cache hint indicating that it will no longer access a block.

Remove LPES1 from the LPCR: Eliminates the capability to request the processor to behave as previous versions of the architecture required when LPES1 = 0.

Split Endian Control: Adds a new MSR bit (SLE) as well as the mtisle instruction which allows its manipulation in problem state. This bit now allows the Endian values used for data and instruction storage accesses to be specified independently.

Direct Move Instructions: Adds new VSX instructions which remove the restriction of cross-register file moves.

Move dnh from Enhanced Debug to Embedded Category: The dnh instruction has been moved to the Embedded category.

Real Mode Storage Control for Instruction Fetching and Loosely-Related Caching-Inhibited Load/Store Changes: Defines an alternative to the existing instruction fetch RMSC approach whereby a first access to a region of storage will be performed as guarded, but subsequent accesses will be performed as non-guarded based on the success of the first.

Elemental Memory Barriers: Extends the definition of the existing sync instruction by adding several memory ordering functions.

Event-Based Branch Facility: A problem-state accessible event-based branch mechanism analogous to the interrupt mechanism is defined.

Stream Prefetch Changes: Allows DSCR access in problem state and adds additional stream prefetch functionality.

Add lqarx/stqcx. Instructions: Adds support for quad-word atomic storage operations.

Allow lq/stq in Problem State: Allows problem state software to use the lq and stq instructions.

Allow lq/stq in Little-Endian Mode: Removes the restriction that the lq and stq instructions can only operate in Big-Endian mode.

Add makeitso Instruction: Adds the miso extended mnemonic which allows producers in producer-consumer applications to provide a hint to push store data out.

Branch Conditional to Target Address Register: Defines a new instruction which branches conditionally to an address contained in a new SPR.

Remove DABR[X], add DAWR[X] and IABR SPRs: Removes and replaces existing DABR/DABRX SPRs with enhanced watchpoint functionality. Additionally adds instruction address breakpoint capability to the ISA.

Facility Availability Registers and Interrupts: A privileged register and a hypervisor register that enables various facilities are defined.

Reserved SPRs: Defines a set of reserved SPRs treated as no-ops in the current architecture so that
exploitation of new function in future designs can proceed more quickly and pervasively.

**Instruction Counter and Virtual Time Base**: Two registers, one that counts instructions completed by a thread, and another that counts at the same rate as the Time Base are added.

**Architecture Changes to Support Program Portability**: Eliminates software exposure to errors caused by variations in behavior due to implementation-dependent bits in CTRL and PPR.

**Miscellaneous Changes**: Various minor editorial corrections are made.

**Interrupts and Relocation, MMIO Emulation**: NewLPCR bits enable most interrupts to be taken with relocation on, and virtual page class key faults to cause Hypervisor Data Storage interrupts.

**Guest Timer Interrupts and Facilities**: Adds guest timer facilities to enable performance measurements for guest operating systems.

**VSX Unaligned Vector Storage Accesses**: Change VSX vector storage access instructions to support to byte-aligned addresses. Simplify Table 2, “Effect of Operand Placement on Performance,” on page 753 in Book II.

**VMX Miscellaneous Operations II**: Adds new instructions `vclzd`, `vpopcntb`, `vpopcnth`, `vpopcntw`, `vpopcntd`, `veqv`, `vnand`, and `vorc`.

**BFP/VSX Miscellaneous Operations**: Introduces new VSX instructions to address IEEE-754-2008 compliance when performing simple assignments between single-precision scalar and vector elements.

**VMX 32-bit Multiply Operations**: Introduces 4-way SIMD 32-bit integer multiply instructions.

**VMX Decimal Integer Operations**: Introduces new packed decimal add and subtract instructions.

**Remove Data Value Compare**: Since the data value compare function can be easily emulated within a data address compare handler, the data value compare registers are removed from Book III-E.

**VMX 128-bit Integer Operations**: Introduces new quad-word integer add and subtract instructions.

**Cache Lock Query Instructions**: Adds instructions to determine whether a cache block has been successfully locked with a preceding cache locking instruction.

**Embedded Guest Performance Monitor Interrupt**: Introduces a new Performance Monitor Interrupt that enables a Performance Monitor interrupt to be taken in guest state.

Book III-S:

Power ISA Operating Environment Architecture - Server Environment [Category: Server] 837

Chapter 1. Introduction 839

1.1 Overview 839
1.2 Document Conventions 839
1.2.1 Definitions and Notation 839
1.2.2 Reserved Fields 840
1.3 General Systems Overview 840
1.4 Exceptions 841
1.5 Synchronization 841
1.5.1 Context Synchronization 841
1.5.2 Execution Synchronization 842
Chapter 2. Logical Partitioning (LPAR) and Thread Control . . . . . 843
  2.1 Overview ...................................... 843
  2.2 Logical Partitioning Control Register (LPCCR) ............... 843
  2.3 Real Mode Offset Register (RMOR) .......................... 846
  2.4 Hypervisor Real Mode Offset Register (HRMOR) ............... 846
  2.5 Logical Partition Identification Register (LPIDR) .............. 847
  2.6 Processor Compatibility Register (PCR) [Category: Processor Compatibility] 847
  2.7 Other Hypervisor Resources ............................... 853
  2.8 Sharing Hypervisor Resources ............................... 854
  2.9 Sub-Processors ...................................... 854
  2.10 Thread Identification Register (TIR) [Category: Server.Processor Control] 854
  2.11 Hypervisor Interrupt Little-Endian (HILE) Bit ................. 855

Chapter 3. Branch Facility . . . . . . 857
  3.1 Branch Facility Overview ................................ 857
  3.2 Branch Facility Registers ................................. 857
  3.2.1 Machine State Register ............................... 857
  3.2.2 State Transitions Associated with the Transactional Memory Facility [Category: Transactional Memory] 860
  3.3 Branch Facility Instructions ............................... 863
  3.3.1 System Linkage Instructions ......................... 863
  3.3.2 Power-Saving Mode Instructions ........................ 866
  3.3.2.1 Entering and Exiting Power-Saving Mode .............. 869
  3.4 Event-Based Branch Facility and Instruction ................ 870

Chapter 4. Fixed-Point Facility . . . . . . 871
  4.1 Fixed-Point Facility Overview ............................ 871
  4.2 Special Purpose Registers ............................... 871
  4.3 Fixed-Point Facility Registers ............................ 871
  4.3.1 Processor Version Register ............................ 871
  4.3.2 Chip Information Register ............................ 871
  4.3.3 Processor Identification Register ..................... 871
  4.3.4 Control Register ..................................... 872
  4.3.5 Program Priority Register ............................ 872
  4.3.6 Problem State Priority Boost Register ................. 873
  4.3.7 Relative Priority Register ............................ 873
  4.3.8 Software-use SPRs ................................. 873
  4.4 Fixed-Point Facility Instructions ........................ 875
  4.4.1 Fixed-Point Load and Store Caching Inhibited Instructions 875
  4.4.2 OR Instruction ..................................... 878
  4.4.3 Transactional Memory Instructions [Category: Transactional Memory] 879
  4.4.4 Move To/From System Register Instructions .............. 880

Chapter 5. Storage Control . . . . . . 889
  5.1 Overview ......................................... 889
  5.2 Storage Exceptions .................................... 889
  5.3 Instruction Fetch ...................................... 889
  5.3.1 Implicit Branch .................................... 889
  5.3.2 Address Wrapping Combined with Changing MSR Bit SF .... 889
  5.4 Data Access ......................................... 889
  5.5 Performing Operations Out-of-Order ........................ 890
  5.6 Invalid Real Address .................................. 890
  5.7 Storage Addressing .................................... 891
  5.7.1 32-Bit Mode ....................................... 891
  5.7.2 Virtualized Partition Memory (VPM) Mode ............... 891
  5.7.3 Real And Virtual Real Addressing Modes ................. 891
  5.7.3.1 Hypervisor Offset Real Mode Address ................ 892
  5.7.3.2 Offset Real Mode Address .......................... 892
  5.7.3.3 Storage Control Attributes for Accesses in Real and Hypervisor Real Addressing Modes ............... 893
  5.7.3.3.1 Hypervisor Real Mode Storage Control ............. 893
  5.7.3.4 Virtual Real Mode Addressing Mechanism ............. 894
  5.7.3.5 Storage Control Attributes for Implicit Storage Accesses 895
  5.7.4 Address Ranges Having Defined Uses ..................... 895
  5.7.5 Address Translation Overview ........................ 895
  5.7.6 Virtual Address Generation ............................ 896
  5.7.6.1 Segment Lookaside Buffer (SLB) ........................ 896
  5.7.6.2 SLB Search ...................................... 897
  5.7.7 Virtual to Real Translation ............................ 898
  5.7.7.1 Page Table ...................................... 900
  5.7.7.2 Storage Description Register 1 ....................... 901
  5.7.7.3 Page Table Search ................................ 902
  5.7.7.4 Relaxed Page Table Alignment [Category: Server.Relaxed Page Table Alignment] ..................... 904
  5.7.8 Reference and Change Recording ........................ 904
  5.7.9 Storage Protection ................................... 908
  5.7.9.1 Virtual Page Class Key Protection .................... 908
  5.7.9.2 Basic Storage Protection, Address Translation Enabled ........................................... 912
5.7.9.3 Basic Storage Protection, Address Translation Disabled .......... 913
5.8 Storage Control Attributes .......... 914
5.8.1 Guarded Storage .......... 914
5.8.1.1 Out-of-Order Accesses to Guarded Storage .......... 914
5.8.2 Storage Control Bits .......... 914
5.8.2.1 Storage Control Bit Restrictions .......... 915
5.8.2.2 Altering the Storage Control Bits .......... 915
5.9 Storage Control Instructions .......... 917
5.9.1 Cache Management Instructions 917
5.9.2 Synchronize Instruction .......... 917
5.9.3 Lookaside Buffer Management .......... 918
5.9.3.1 SLB Management Instructions 918
5.9.3.2 Bridge to SLB Architecture [Category: Server.Phased-Out] .......... 925
5.9.3.2.1 Segment Register Manipulation Instructions .......... 925
5.9.3.3 TLB Management Instructions 928
5.10 Page Table Update Synchronization Requirements .......... 935
5.10.1 Page Table Updates .......... 935
5.10.1.1 Adding a Page Table Entry .......... 936
5.10.1.2 Modifying a Page Table Entry 937
5.10.1.3 Deleting a Page Table Entry 937

Chapter 6. Interrupts .......... 939
6.1 Overview .......... 939
6.2 Interrupt Registers .......... 939
6.2.1 Machine Status Save/Restore Registers .......... 939
6.2.2 Hypervisor Machine Status Save/Restore Registers .......... 939
6.2.3 Data Address Register .......... 939
6.2.4 Hypervisor Data Address Register .......... 940
6.2.5 Data Storage Interrupt Status Register .......... 940
6.2.6 Hypervisor Data Storage Interrupt Status Register .......... 940
6.2.7 Hypervisor Emulation Instruction Register .......... 940
6.2.8 Hypervisor Maintenance Exception Register .......... 940
6.2.9 Hypervisor Maintenance Exception Enable Register .......... 941
6.2.10 Facility Status and Control Register .......... 941
6.2.11 Hypervisor Facility Status and Control Register .......... 942
6.3 Interrupt Synchronization .......... 946
6.4 Interrupt Classes .......... 946
6.4.1 Precise Interrupt .......... 946
6.4.2 Imprecise Interrupt .......... 946
6.4.3 Interrupt Processing .......... 947
6.4.4 Implicit alteration of HSRR0 and HSRR1 .......... 949
6.5 Interrupt Definitions .......... 950
6.5.1 System Reset Interrupt .......... 952
6.5.2 Machine Check Interrupt .......... 953
6.5.3 Data Storage Interrupt .......... 955
6.5.4 Data Segment Interrupt .......... 956
6.5.5 Instruction Storage Interrupt .......... 957
6.5.6 Instruction Segment Interrupt .......... 957
6.5.7 External Interrupt .......... 957
6.5.8 Alignment Interrupt .......... 957
6.5.9 Program Interrupt .......... 959
6.5.10 Floating-Point Unavailable Interrupt .......... 961
6.5.11 Decrementer Interrupt .......... 961
6.5.12 Hypervisor Decrementer Interrupt .......... 961
6.5.13 Directed Privileged Doorbell Interrupt [Category: Server.Processor Control] .......... 962
6.5.14 System Call Interrupt .......... 962
6.5.15 Trace Interrupt [Category: Trace] .......... 962
6.5.16 Hypervisor Data Storage Interrupt .......... 963
6.5.17 Hypervisor Instruction Storage Interrupt .......... 964
6.5.18 Hypervisor Emulation Assistance Interrupt .......... 965
6.5.19 Hypervisor Maintenance Interrupt .......... 965
6.5.20 Directed Hypervisor Doorbell Interrupt [Category: Server.Processor Control] .......... 966
6.5.22 Vector Unavailable Interrupt [Category: Vector] .......... 966
6.5.23 VSX Unavailable Interrupt [Category: VSX] .......... 966
6.5.24 Facility Unavailable Interrupt .......... 967
6.5.25 Hypervisor Facility Unavailable Interrupt .......... 967
6.6 Partially Executed Instructions .......... 968
6.7 Exception Ordering .......... 969
6.7.1 Unordered Exceptions .......... 969
6.7.2 Ordered Exceptions .......... 969
6.8 Interrupt Priorities .......... 970
6.9 Relationship of Event-Based Branches to Interrupts .......... 972
## Chapter 2. Registers

- 2.2 Registers ........................................... 1027
- 2.2.1 Register Mapping ................................. 1027
- 2.2.2 Logical Partition Identification Register (LPIDR) ........... 1028
- 2.3 Interrupts and Exceptions .......................... 1028
- 2.3.1 Directed Interrupts ............................... 1028
- 2.3.2 Hypervisor Service Interrupts .................... 1029
- 2.4 Instruction Mapping ................................ 1029

## Chapter 3. Thread Control [Category: Embedded Multi-Threading] ...

- 3.1 Overview ............................................ 1031
- 3.2 Thread Identification Register (TIR) .................. 1031
- 3.3 Thread Enable Register (TEN) ....................... 1031
- 3.4 Thread Enable Status Register (TENSR) ............... 1031
- 3.5 Disabling and Enabling Threads....................... 1032
- 3.6 Sharing of Multi-Threaded Processor Resources .......... 1032
- 3.7 Thread Management Facility [Category: Embedded Multithreading:Thread Management] ........ 1033
- 3.7.1 Initialize Next Instruction Address Registers .......... 1033
- 3.7.2 Thread Management Instructions .................. 1034

## Chapter 4. Branch Facility ....... 1035

- 4.1 Branch Facility Overview .......................... 1035
- 4.2 Branch Facility Registers .......................... 1035
- 4.2.1 Machine State Register .......................... 1035
- 4.2.2 Machine State Register Protect Register (MSRP) ....... 1037
- 4.2.3 Embedded Processor Control Register (EPCR) .......... 1038
- 4.3 Branch Facility Instructions ........................ 1040
- 4.3.1 System Linkage Instructions ........................ 1040

## Chapter 5. Fixed-Point Facility . 1045

- 5.1 Fixed-Point Facility Overview ....................... 1045
- 5.2 Special Purpose Registers .......................... 1045
- 5.3 Fixed-Point Facility Registers ....................... 1045
- 5.3.1 Processor Version Register ........................ 1045
- 5.3.2 Chip Information Register ........................ 1045
- 5.3.3 Processor Identification Register .................. 1045
- 5.3.4 Guest Processor Identification Register [Category: Embedded.Hypervisor] .................. 1046
- 5.3.5 Program Priority Register 32-bit .................. 1046
- 5.3.6 Software-use SPRs ................................ 1046
- 5.3.7 External Process ID Registers [Category: Embedded.External PID] .................. 1048

## Chapter 6. Storage Control ....... 1073

- 6.1 Overview ............................................ 1073
- 6.2 Storage Exceptions ................................ 1075
- 6.3 Instruction Fetch ................................... 1075
- 6.3.1 Implicit Branch .................................. 1075
- 6.3.2 Address Wrapping Combined with Changing MSR Bit CM ........ 1076
- 6.4 Data Access ........................................ 1076
- 6.5 Performing Operations Out-of-Order .................. 1076
- 6.6 Invalid Real Address ............................... 1077
- 6.7 Storage Control ..................................... 1077
- 6.7.1 Translation Lookaside Buffer ..................... 1077
- 6.7.2 Virtual Address Spaces ........................... 1081
- 6.7.3 TLB Address Translation ......................... 1082
- 6.7.4 Page Table Address Translation [Category: Embedded.Page Table] ........ 1085
- 6.7.5 Page Table Update Synchronization Requirements [Category: Embedded.Page Table] ........ 1092
- 6.7.5.1 Page Table Updates ............................ 1093
- 6.7.5.1.1 Adding a Page Table Entry .................. 1093
- 6.7.5.1.2 Deleting a Page Table Entry ................. 1094
- 6.7.5.1.3 Modifying a Page Table Entry ............... 1094
- 6.7.5.2 Invalidating an Indirect TLB Entry ................. 1094
- 6.7.6 Storage Access Control ......................... 1094
- 6.7.6.1 Execute Access ............................... 1095
- 6.7.6.2 Write Access .................................. 1095
- 6.7.6.3 Read Access .................................. 1095
- 6.7.6.4 Virtualized Access <E.HV> .......... 1096
- 6.7.6.5 Storage Access Control Applied to Cache Management Instructions ........ 1096
- 6.7.6.6 Storage Access Control Applied to String Instructions .................. 1096
- 6.8 Storage Control Attributes ....................... 1097
- 6.8.1 Guarded Storage ................................ 1097
- 6.8.1.1 Out-of-Order Accesses to Guarded Storage ........ 1097
- 6.8.2 User-Definable .................................. 1097
- 6.8.3 Storage Control Bits ............................. 1097
- 6.8.3.1 Storage Control Bit Restrictions ............... 1098

## Chapter 7. Interrupts and Exceptions

7.1 Overview                                                        | 1145 |
7.2 Interrupt Registers                                              | 1145 |
7.2.1 Save/Restore Register 0                                         | 1145 |
7.2.2 Save/Restore Register 1                                         | 1145 |
7.2.3 Guest Save/Restore Register 0 [Category: Embedded.Hypervisor] | 1146 |
7.2.4 Guest Save/Restore Register 1 [Category: Embedded.Hypervisor] | 1146 |
7.2.5 Critical Save/Restore Register 0                               | 1147 |
7.2.6 Critical Save/Restore Register 1                               | 1147 |
7.2.7 Debug Save/Restore Register 0 [Category: Embedded.Enhanced Debug] | 1147 |
7.2.8 Debug Save/Restore Register 1 [Category: Embedded.Enhanced Debug] | 1148 |
7.2.9 Data Exception Address Register                                | 1148 |
7.2.10 Guest Data Exception Address Register [Category: Embedded.Hypervisor] | 1148 |
7.2.11 Interrupt Vector Prefix Register                              | 1148 |
7.2.12 Guest Interrupt Vector Prefix Register [Category: Embedded.Hypervisor] | 1149 |
7.2.13 Exception Syndrome Register                                   | 1150 |
7.2.14 Guest Exception Syndrome Register [Category: Embedded.Hypervisor] | 1151 |
7.2.15 Interrupt Vector Offset Registers [Category: Embedded.Phased-Out] | 1151 |
7.2.16 Guest Interrupt Vector Offset Register [Category: Embedded.Hypervisor.Phased-Out] | 1152 |
7.2.17 Logical Page Exception Register [Category: Embedded.Hypervisor and Embedded.Page Table] | 1153 |
11.2.2.2 Guest Doorbell Message Filtering [Category: Embedded.Hypervisor] 1231
11.2.2.3 Guest Doorbell Critical Message Filtering [Category: Embedded.Hypervisor] 1232
11.2.2.4 Guest Doorbell Machine Check Message Filtering [Category: Embedded.Hypervisor] 1232
11.3 Processor Control Instructions 1233

Chapter 12. Synchronization
Requirements for Context Alterations 1235

Appendix
A. Implementation-Dependent Instructions 1239
   A.1 Embedded Cache Initialization [Category: Embedded.Cache Initialization] 1239
   A.2 Embedded Cache Debug Facility [Category: Embedded.Cache Debug] 1240
   A.2.1 Embedded Cache Debug Registers 1240
      A.2.1.1 Data Cache Debug Tag Register High 1240
      A.2.1.2 Data Cache Debug Tag Register Low 1240
      A.2.1.3 Instruction Cache Debug Data Register 1241
      A.2.1.4 Instruction Cache Debug Tag Register High 1241
      A.2.1.5 Instruction Cache Debug Tag Register Low 1241
      A.2.2 Embedded Cache Debug Instructions 1242

Appendix B. Assembler Extended Mnemonics 1245
   B.1 Move To/From Special Purpose Register Mnemonics 1246
   B.2 Data Cache Block Flush Mnemonics [Category: Embedded.Phased In] 1247

Appendix C. Guidelines for 64-bit Implementations in 32-bit Mode and 32-bit Implementations 1249
   C.1 Hardware Guidelines 1249
      C.1.1 64-bit Specific Instructions 1249
      C.1.2 Registers on 32-bit Implementations 1249
      C.1.3 Addressing on 32-bit Implementations 1249
   C.1.4 TLB Fields on 32-bit Implementations 1249
   C.1.5 Thread Control and Status on 32-bit Implementations 1249
   C.2 32-bit Software Guidelines 1249
      C.2.1 32-bit Instruction Selection 1249

Appendix D. Example Performance Monitor [Category: Embedded.Performance Monitor] 1251
   D.1 Overview 1251
   D.2 Programming Model 1251
      D.2.1 Event Counting 1252
      D.2.2 Thread Context Configurability 1252
      D.2.3 Event Selection 1252
      D.2.4 Thresholds 1253
      D.2.5 Performance Monitor Exception 1253
      D.2.6 Performance Monitor Interrupt 1253
      D.3 Performance Monitor Registers 1253
      D.3.1 Performance Monitor Global Control Register 0 1253
      D.3.2 Performance Monitor Local Control A Registers 1254
      D.3.3 Performance Monitor Local Control B Registers 1255
      D.3.4 Performance Monitor Counter Registers 1255
      D.4 Performance Monitor Instructions 1257
      D.5 Performance Monitor Software Usage Notes 1258
      D.5.1 Chaining Counters 1258
      D.5.2 Thresholding 1258

Book VLE:

Chapter 1. Variable Length Encoding Introduction 1261
   1.1 Overview 1261
   1.2 Documentation Conventions 1261
      1.2.1 Description of Instruction Operation 1261
   1.3 Instruction Mnemonics and Operands 1261
      1.4 VLE Instruction Formats 1262
Appendix A. VLE Instruction Set
Sorted by Mnemonic .......................... 1315

Appendix B. VLE Instruction Set
Sorted by Opcode ............................ 1331

Appendices:

Power ISA Book I-III Appendices 1347

Appendix A. Incompatibilities with
the POWER Architecture ................. 1349
  A.1 New Instructions, Formerly Privileged
      Instructions ............................ 1349
  A.2 Newly Privileged
      Instructions ............................ 1349
  A.3 Reserved Fields in
      Instructions ............................ 1349
  A.4 Reserved Bits in Registers .......... 1349
  A.5 Alignment Check ........................ 1349
  A.6 Condition Register .................... 1350
  A.7 LK and Rc Bits ........................ 1350
  A.8 BO Field ............................... 1350
  A.9 BH Field ............................... 1350
  A.10 Branch Conditional to Count Register
       ........................................ 1350
  A.11 System Call ........................... 1350
  A.12 Fixed-Point Exception
      Register (XER) ......................... 1351
  A.13 Update Forms of Storage Access
      Instructions ........................... 1351
  A.14 Multiple Register Loads .......... 1351
  A.15 Load/Store Multiple Instructions 1351
  A.16 Move Assist Instructions ........... 1351
  A.17 Move To/From SPR .................... 1351
  A.18 Effects of Exceptions on FPSCR Bits
      FR and FI ............................... 1352
  A.19 Store Floating-Point Single Instruc-
      tions ................................. 1352
  A.20 Move From FPSCR ..................... 1352
  A.21 Zeroing Bytes in the Data Cache ....
       ........................................ 1352
  A.22 Synchronization ...................... 1352
  A.23 Move To Machine State Register
      Instruction ............................ 1352
  A.24 Direct-Store Segments ............... 1352
  A.25 Segment Register
      Manipulation Instructions ............. 1352
  A.26 TLB Entry Invalidation .......... 1353
  A.27 Alignment Interrupts ............... 1353
  A.28 Floating-Point Interrupts .......... 1353
  A.29 Timing Facilities .................... 1353
  A.29.1 Real-Time Clock ................... 1353
  A.29.2 Decrementer ....................... 1353
  A.30 Deleted Instructions ............... 1354
  A.31 Discontinued Opcodes ............... 1354
  A.32 POWER2 Compatibility ............... 1355
  A.32.1 Cross-Reference for Changed
       POWER2 Mnemonics .................... 1355
  A.32.2 Load/Store Floating-Point Double...
       ........................................ 1355
  A.32.3 Floating-Point Conversion to Inte-
       ger ................................. 1355
  A.32.4 Floating-Point Interrupts ....... 1356
  A.32.5 Trace .............................. 1356
  A.33 Deleted Instructions ............... 1356
  A.33.1 Discontinued Opcodes ............. 1356

Appendix B. Platform Support
Requirements ............................... 1357

Appendix C. Complete SPR List 1361

Appendix D. Illegal Instructions 1367

Appendix E. Reserved Instructions .. 1369

Appendix F. Opcode Maps ............... 1371

Appendix G. Power ISA Instruction
Set Sorted by Category ..................... 1395

Appendix H. Power ISA Instruction
Set Sorted by Opcode ....................... 1425

Appendix I. Power ISA Instruction
Set Sorted by Mnemonic .................... 1455

Book I:

Power ISA User Instruction Set Architecture
Chapter 1. Introduction

1.1 Overview
This chapter describes computation modes, document conventions, a processor overview, instruction formats, storage addressing, and instruction fetching.

1.2 Instruction Mnemonics and Operands
The description of each instruction includes the mnemonic and a formatted list of operands. Some examples are the following.

- `stw RS,D(RA)`
- `addis RT,RA,SI`

Power ISA-compliant Assemblers will support the mnemonics and operand lists exactly as shown. They should also provide certain extended mnemonics, such as the ones described in Appendix E of Book I.

1.3 Document Conventions

1.3.1 Definitions
The following definitions are used throughout this document.

- **program**
  A sequence of related instructions.

- **application program**
  A program that uses only the instructions and resources described in Books I and II.

- **processor**
  The hardware component that implements the instruction set, storage model, and other facilities defined in the Power ISA architecture, and executes the instructions specified in a program.

- **quadwords, doublewords, words, halfwords, and bytes**
  128 bits, 64 bits, 32 bits, 16 bits, and 8 bits, respectively.

- **positive**
  Means greater than zero.

- **negative**
  Means less than zero.

- **floating-point single format** (or simply single format)
  Refers to the representation of a single-precision binary floating-point value in a register or storage.

- **floating-point double format** (or simply double format)
  Refers to the representation of a double-precision binary floating-point value in a register or storage.

- **system library program**
  A component of the system software that can be called by an application program using a Branch instruction.

- **system service program**
  A component of the system software that can be called by an application program using a System Call instruction.

- **system trap handler**
  A component of the system software that receives control when the conditions specified in a Trap instruction are satisfied.

- **system error handler**
  A component of the system software that receives control when an error occurs. The system error handler includes a component for each of the various kinds of error. These error-specific components are referred to as the system alignment error handler, the system data storage error handler, etc.

- **latency**
  Refers to the interval from the time an instruction begins execution until it produces a result that is available for use by a subsequent instruction.

- **unavailable**
  Refers to a resource that cannot be used by the program. For example, storage is unavailable if access to it is denied. See Book III.
undefined value
May vary between implementations, and between different executions on the same implementation, and similarly for register contents, storage contents, etc., that are specified as being undefined.

boundedly undefined
The results of executing a given instruction are said to be boundedly undefined if they could have been achieved by executing an arbitrary finite sequence of instructions (none of which yields boundedly undefined results) in the state the processor was in before executing the given instruction. Boundedly undefined results may include the presentation of inconsistent state to the system error handler as described in Section 1.9.1 of Book II. Boundedly undefined results for a given instruction may vary between implementations, and between different executions on the same implementation.

“must”
If software violates a rule that is stated using the word “must” (e.g., “this field must be set to 0”), the results are boundedly undefined unless otherwise stated.

sequential execution model
The model of program execution described in Section 2.2, “Instruction Execution Order” on page 29.

Auxiliary Processor
An implementation-specific processing unit. Previous versions of the architecture use the term Auxiliary Processing Unit (APU) to describe this extension of the architecture. Architectural support for auxiliary processors is part of the Embedded category.

virtualized implementation
An implementation of the Power Architecture created by hypervisor software. A guest operating system sees a virtualized implementation of the Power ISA. Architectural support for virtualized implementations is part of the Embedded category (see Section 1.3.5, “Categories”).

1.3.2 Notation
The following notation is used throughout the Power ISA documents.

- All numbers are decimal unless specified in some special way.
  - 0bnnnn means a number expressed in binary format.
  - 0xnnnn means a number expressed in hexadecimal format.
  Underscores may be used between digits.
- RT, RA, R1, ... refer to General Purpose Registers.
- FRT, FRA, FR1, ... refer to Floating-Point Registers.
- FRTp, FRAp, FRBp, ... refer to an even-odd pair of Floating-Point Registers. Values must be even, otherwise the instruction form is invalid.
- VRT, VRA, VR1, ... refer to Vector Registers.
- (x) means the contents of register x, where x is the name of an instruction field. For example, (RA) means the contents of register RA, and (FRA) means the contents of register FRA, where RA and FRA are instruction fields. Names such as LR and CTR denote registers, not fields, so parentheses are not used with them. Parentheses are also omitted when register x is the register into which the result of an operation is placed.
- (RA/0) means the contents of register RA if the RA field has the value 1-31, or the value 0 if the RA field is 0.
- Bytes in instructions, fields, and bit strings are numbered from left to right, starting with byte 0 (most significant).
- Bits in registers, instructions, fields, and bit strings are specified as follows. In the last three items (definition of Xp etc.), if X is a field that specifies a GPR, FPR, or VR (e.g., the RS field of an instruction), the definitions apply to the register, not to the field.
  - Bits in instructions, fields, and bit strings are numbered from left to right, starting with bit 0
  - For all registers except the Vector category, bits in registers that are less than 64 bits start with bit number 64-L, where L is the register length; for the Vector category, bits in registers that are less than 128 bits start with bit number 128-L.
  - The leftmost bit of a sequence of bits is the most significant bit of the sequence.
  - Xp means bit p of register/instruction/field/bit_string X.
  - Xp:q means bits p through q of register/instruction/field/bit_string X.
  - Xp q ... means bits p, q, ... of register/instruction/field/bit_string X.
- ¬(RA) means the one’s complement of the contents of register RA.
- A period (.) as the last character of an instruction mnemonic means that the instruction records status information in certain fields of the Condition Register as a side effect of execution.
- The symbol ‖ is used to describe the concatenation of two values. For example, 010 ‖ 111 is the same as 010111.
- x^n means x raised to the n^th power.
nx means the replication of x, n times (i.e., x concatenated to itself n–1 times). n0 and n1 are special cases:
- n0 means a field of n bits with each bit equal to 0. Thus n0 is equivalent to 0b00000.
- n1 means a field of n bits with each bit equal to 1. Thus n1 is equivalent to 0b11111.

Each bit and field in instructions, and in status and control registers (e.g., XER, FPSCR) and Special Purpose Registers, is either defined or reserved. Some defined fields contain reserved values. In such cases when this document refers to the specific field, it refers only to the defined values, unless otherwise specified.

/, //, ///, ... denotes a reserved field, in a register, instruction, field, or bit string.

?, ??, ???, ... denotes an implementation-dependent field in a register, instruction, field or bit string.

1.3.3 Reserved Fields, Reserved Values, and Reserved SPRs

Reserved fields in instructions are ignored by the processor. This is a requirement in the Server environment and is being phased into the Embedded environment.

In some cases a defined field of an instruction has certain values that are reserved. This includes cases in which the field is shown in the instruction layout as containing a particular value; in such cases all other values of the field are reserved. In general, if an instruction is coded such that a defined field contains a reserved value the instruction form is invalid; see Section 1.8.2 on page 22. The only exceptions to the preceding rule is that it does not apply to Reserved and Illegal classes of instructions (see Section 1.7) or to portions of defined fields that are specified, in the instruction description, as being treated as reserved fields.

To maximize compatibility with future architecture extensions, software must ensure that reserved fields in instructions contain zero and that defined fields of instructions do not contain reserved values.

The handling of reserved bits in System Registers (e.g., XER, FPSCR) depends on whether the processor is in problem state. Unless otherwise stated, software is permitted to write any value to such a bit. In problem state, a subsequent reading of the bit returns 0 regardless of the value written; in privileged states, a subsequent reading of the bit returns 0 if the value last written to the bit was 0 and returns an undefined value (0 or 1) otherwise.

In some cases, a defined field of a System Register has certain values that are reserved. Software must not set a defined field of a System Register to a reserved value. References elsewhere in this document to a defined field (in an instruction or System Register) that has reserved values assume the field does not contain a reserved value, unless otherwise stated or obvious from context.

In some cases, a given bit of a System Register is specified to be set to a constant value by a given instruction or event. Unless otherwise stated or obvious from context, software should not depend on this constant value because the bit may be assigned a meaning in a future version of the architecture.

The reserved SPRs include SPRs 808, 809, 810, and 811. mtspr and mfspr instructions specifying these SPRs are treated as noops. Reserved SPRs are provided in the architecture to anticipate the eventual adoption of performance hint functionality that must be controlled by SPRs. Control of these capabilities using reserved SPRs will allow software to use these new capabilities on new implementations that support them while remaining compatible with existing implementations that may not support the new functionality.
Reserved SPRs are not assigned names. There are no individual descriptions of reserved SPRs in this document.

**Assembler Note**

Assemblers should report uses of reserved values of defined fields of instructions as errors.

**Programming Note**

It is the responsibility of software to preserve bits that are now reserved in System Registers, because they may be assigned a meaning in some future version of the architecture.

In order to accomplish this preservation in implementation-independent fashion, software should do the following.

- Initialize each such register supplying zeros for all reserved bits.
- Alter (defined) bit(s) in the register by reading the register, altering only the desired bit(s), and then writing the new value back to the register.

The XER and FPSCR are partial exceptions to this recommendation. Software can alter the status bits in these registers, preserving the reserved bits, by executing instructions that have the side effect of altering the status bits. Similarly, software can alter any defined bit in the FPSCR by executing a Floating-Point Status and Control Register instruction. Using such instructions is likely to yield better performance than using the method described in the second item above.

### 1.3.4 Description of Instruction Operation

Instruction descriptions (including related material such as the introduction to the section describing the instructions) mention that the instruction may cause a system error handler to be invoked, under certain conditions, if and only if the system error handler may treat the case as a programming error. (An instruction may cause a system error handler to be invoked under other conditions as well; see Chapter 6 of Book III-S and Chapter 7 of Book III-E).

A formal description is given of the operation of each instruction. In addition, the operation of most instructions is described by a semiformal language at the register transfer level (RTL). This RTL uses the notation given below, in addition to the notation described in Section 1.3.2. Some of this notation is also used in the formal descriptions of instructions. RTL notation not summarized here should be self-explanatory.

The RTL descriptions cover the normal execution of the instruction, except that “standard” setting of status registers, such as the Condition Register, is not shown. (“Non-standard” setting of these registers, such as the setting of the Condition Register by the Compare instructions, is shown.) The RTL descriptions do not cover cases in which the system error handler is invoked, or for which the results are boundedly undefined.

The RTL descriptions specify the architectural transformation performed by the execution of an instruction. They do not imply any particular implementation.

</table>
MASK(x, y) Mask having 1s in positions x through y (wrapping if x > y) and 0s elsewhere

MEM(x, y) Contents of a sequence of y bytes of storage. The sequence depends on the byte ordering used for storage access, as follows.
  Big-Endian byte ordering:
  The sequence starts with the byte at address x and ends with the byte at address x+y-1.
  Little-Endian byte ordering:
  The sequence starts with the byte at address x+y-1 and ends with the byte at address x.

MEM_DECORATED(x, y, z)
Contents of a sequence of y bytes of storage, where the storage is accessed with decoration z applied. The sequence depends on the byte ordering used for storage access, as follows.
  Big-Endian byte ordering:
  The sequence starts with the byte at address x and ends with the byte at address x+y-1.
  Little-Endian byte ordering:
  The sequence starts with the byte at address x+y-1 and ends with the byte at address x.

MEM_NOTIFY(x, z)
The decoration z is sent to storage location x.

ROTL64(x, y) Result of rotating the 64-bit value x left y positions

ROTL32(x, y) Result of rotating the 64-bit value x||x left y positions, where x is 32 bits long

SINGLE(x) Result of converting x from floating-point double format to floating-point single format, using the model shown on page 137

SPR(x) Special Purpose Register x

switch/case/default statement, indenting shows range. The clause after “switch” specifies the expression to evaluate. The clause after “case” specifies individual values for the expression, followed by a colon, followed by the actions that are taken if the evaluated expression has any of the specified values. “default” is optional. If present, it must follow all the “case” clauses. The clause after “default” starts with a colon, and specifies the actions that are taken if the evaluated expression does not have any of the values specified in the preceding case statements.

TRAP Invoke the system trap handler

Characterization
Reference to the setting of status bits, in a standard way that is explained in the text

undefined An undefined value.
The precedence rules for RTL operators are summarized in Table 1. Operators higher in the table are applied before those lower in the table. Operators at the same level in the table associate from left to right, from right to left, or not at all, as shown. (For example, \(-\) associates from left to right, so \(a-b-c = (a-b)-c\).)

Parentheses are used to override the evaluation order implied by the table or to increase clarity; parenthesized expressions are evaluated before serving as operands.

### 1.3.5 Categories

Each facility (including registers and fields therein) and instruction is in exactly one of the categories listed in Figure 1.

A category may be defined as a dependent category. These are categories that are supported only if the category they are dependent on is also supported. Dependent categories are identified by the “*” in their category name, e.g., if an implementation supports the Floating-Point.Record category, then the Floating-Point category is also supported.

An implementation that supports a facility or instruction in a given category, except for the two categories

¹ Because of overlapping opcode usage, SPE is mutually exclusive with Vector and with Legacy Integer Multiply-Accumulate, and Legacy Integer Multiply-Accumulate is mutually exclusive with Vector.

² The SPE-dependent Floating-Point categories are collectively referred to as SPE.Embedded Float_* or SP.*.

Figure 1. Category Listing (Sheet 2 of 2)

An instruction in a category that is not supported by the implementation is treated as an illegal instruction or an unimplemented instruction on that implementation (see Section 1.7.2).

For an instruction that is supported by the implementation with field values that are defined by the architecture, the field values defined as part of a category that is not supported by the implementation are treated as reserved values on that implementation (see Section 1.3.3 and Section 1.8.2).

Bits in a register that are in a category that is not supported by the implementation are treated as reserved.

1.3.5.1 Phased-In/Phased-Out

There are two special categories, Phased-In and Phased-Out, as well as two additional variations of Phased-In as defined below. Abbreviations, if applicable, are shown in parentheses.

Phased-In
These are facilities and instructions that, in the next version of the architecture, will be required as part of the category they are dependent on.

Servers do not implement a facility or instruction in this category. Servers that comply with earlier versions of this architecture may have optionally implemented facilities or instructions that were category Phased-In.

Server, Embedded.Phased-In (S,E.PI)

These are facilities and instructions that are part of the Server environment and, in the next version of the architecture, will be required for the Embedded environment.

It is implementation-dependent whether Embedded processors implement a facility or instruction in this category.

Embedded, Server.Phased-In (E,S.PI)

These are facilities and instructions that are part of the Embedded environment and, in the next version of the architecture, will be required for the Server environment.

Servers do not implement a facility or instruction in this category.

Phased-Out

These are facilities and instructions that, in some future version of the architecture, will be dropped out of the architecture. System developers should develop a migration plan to eliminate use of them in new systems.

For Server platforms, Phased-Out facilities and instructions must be implemented if the facility or instruction is part of another category (including the Base category) that is supported by the Server platform.

1.3.5.3 Category Notation

Instructions and facilities are considered part of the Base category unless otherwise marked. If a section is marked with a specific category tag, all material in that section and its subsections are considered part of the category, unless otherwise marked. Overview sections may contain discussion of instructions and facilities from various categories without being explicitly marked.

An example of a category tag is: [Category: Server]. Alternatively, a shorthand notation of a category tag includes the category name in angled brackets “<>”, such as <E.HV>.

An example of a dependent category is: [Category: Server.Phased-In]

The shorthand <E> and <S> may also be used for Category: Embedded and Server respectively.

1.3.6 Environments

All implementations support one of the two defined environments, Server or Embedded. Environments refer to common subsets of instructions that are shared across many implementations. The Server environment describes implementations that support Category: Base and Server. The Embedded environment describes implementations that support Category: Base and Embedded.

Warning: Instructions and facilities being phased out of the architecture are likely to perform poorly on future implementations. New programs should not use them.

Facilities are categorized as Phased-In only in cases where there is a difference between the Server and Embedded environments.

1.3.5.2 Corequisite Category

A corequisite category is an additional category that is associated with an instruction or facility, and must be implemented if the instruction or facility is implemented.
1.4 Processor Overview

The basic classes of instructions are as follows:

- branch instructions (Chapter 2)
- GPR-based scalar fixed-point instructions (Chapter 3, Chapter 9, and Chapter 11)
- GPR-based vector fixed-point instructions (Chapter 8)
- GPR-based scalar and vector floating-point instructions (Chapter 10)
- FPR-based scalar floating-point instructions (Chapter 4)
- FPR-based scalar decimal floating-point instructions (Chapter 6)
- VR-based vector fixed-point and floating-point instructions (Chapter 5)
- VSR-based scalar and vector floating-point instructions (Chapter 7)

Scalar fixed-point instructions operate on byte, halfword, word, doubleword, and quadword (see Book III-S) operands, where each operand contained in a GPR. Vector fixed-point instructions operate on vectors of byte, halfword, and word operands, where each vector is contained in a GPR or VR. Scalar floating-point instructions operate on single-precision or double-precision floating-point operands, where each operand is contained in a GPR, FPR, or VSR. Vector floating-point instructions operate on vectors of single-precision and double-precision floating-point operands, where each vector is contained in a GPR, VR, or VSR.

The Power ISA uses instructions that are four bytes long and word-aligned (VLE has different instruction characteristics; see Book VLE). It provides for byte, halfword, word, doubleword, and quadword operand loads and stores between storage and a set of 32 General Purpose Registers (GPRs). It provides for word and doubleword operand loads and stores between storage and a set of 32 Floating-Point Registers (FPRs). It also provides for byte, halfword, word, and quadword operand loads and stores between storage and a set of 32 Vector Registers (VRs). It provides for doubleword and quadword operand loads and stores between storage and a set of 64 Vector-Scalar Registers (VSRs).

Signed integers are represented in two’s complement form.

There are no computational instructions that modify storage; instructions that reference storage may reformat the data (e.g. load halfword algebraic). To use a storage operand in a computation and then modify the same or another storage location, the contents of the storage operand must be loaded into a register, modified, and then stored back to the target location.

Figure 2 is a logical representation of instruction processing. Figure 3 shows the registers that are defined in Book I. (A few additional registers that are available to application programs are defined in other Books, and are not shown in the figure.)

**Category: Vector:**

**Category: Vector-Scalar Extension:**

**Category: SPE:**
1.5 Computation modes

1.5.1 Modes [Category: Server]  
Processors provide two execution modes, 64-bit mode and 32-bit mode. In both of these modes, instructions that set a 64-bit register affect all 64 bits. The computational mode controls how the effective address is interpreted, how Condition Register bits and XER bits are set, how the Link Register is set by Branch instructions in which LK=1, and how the Count Register is tested by Branch Conditional instructions. Nearly all instructions are available in both modes (the only exceptions are a few instructions that are defined in Book III-S). In both modes, effective address computations use all 64 bits of the relevant registers (General Purpose Registers, Link Register, Count Register, etc.) and produce a 64-bit result. However, in 32-bit mode the high-order 32 bits of the computed effective address are ignored for the purpose of addressing storage; see Section 1.10.3 for additional details.

--- Programming Note ---
Although instructions that set a 64-bit register affect all 64 bits in both 32-bit and 64-bit modes, operating systems often do not preserve the upper 32-bits of all registers across context switches done in 32-bit mode. For this reason, application programs operating in 32-bit mode should not assume that the upper 32 bits of the GPRs are preserved from instruction to instruction unless the operating system is known to preserve these bits.

1.5.2 Modes [Category: Embedded]  
64-bit processors provide 64-bit mode and 32-bit mode. The differences between the two modes are described below. 32-bit processors provide only 32-bit mode, and do so as described at the end of this section.

- In 64-bit mode, the processor behaves as described for 64-bit mode in the Server environment; see Section 1.5.1.
- In 32-bit mode, the processor behavior depends on whether the high-order 32 bits of GPRs are implemented in 32-bit mode, as follows.
  - If these bits are implemented in 32-bit mode, the processor behaves as described for 32-bit mode in the Server environment.
  - If these bits are not implemented in 32-bit mode, the processor behaves as described for 32-bit mode in the Server Environment except for the following.

32-bit processors provide only 32-bit mode, and provide it as described by the second sub-bullet of the 32-bit mode bullet above.

1.6 Instruction Formats  
All instructions are four bytes long and word-aligned (except for VLE instructions; see Book VLE). Thus, whenever instruction addresses are presented to the processor (as in Branch instructions) the low-order two bits are ignored. Similarly, whenever the processor develops an instruction address the low-order two bits are zero.

Bits 0:5 always specify the opcode (OPCD, below). Many instructions also have an extended opcode (XO, below). The remaining bits of the instruction contain one or more fields as shown below for the different instruction formats.
The format diagrams given below show horizontally all valid combinations of instruction fields. The diagrams include instruction fields that are used only by instructions defined in Book II or in Book III.

**Split Field Notation**

In some cases an instruction field occupies more than one contiguous sequence of bits, or occupies one contiguous sequence of bits that are used in permuted order. Such a field is called a split field. In the format diagrams given below and in the individual instruction layouts, the name of a split field is shown in small letters, once for each of the contiguous sequences. In the RTL description of an instruction having a split field, and in certain other places where individual bits of a split field are identified, the name of the field in small letters represents the concatenation of the sequences from left to right. In all other places, the name of the field is capitalized and represents the concatenation of the sequences in some order, which need not be left to right, as described for each affected instruction.

### 1.6.28 Instruction Fields

**A (6)**

Field used by the `tbegin` instruction to specify an implementation-specific function.

Field used by the `tend` instruction to specify the completion of the outer transaction and all nested transactions.

**AA (30)**

Absolute Address bit.

0 The immediate field represents an address relative to the current instruction address. For I-form branches the effective address of the branch target is the sum of the LI field sign-extended to 64 bits and the address of the branch instruction. For B-form branches the effective address of the branch target is the sum of the BD field sign-extended to 64 bits and the address of the branch instruction.

1 The immediate field represents an absolute address. For I-form branches the effective address of the branch target is the LI field sign-extended to 64 bits. For B-form branches the effective address of the branch target is the BD field sign-extended to 64 bits.

**AX (29) & A(11:15)**

Fields that are concatenated to specify a VSR to be used as a source.

**BA (11:15)**

Field used to specify a bit in the CR to be used as a source.

**BB (16:20)**

Field used to specify a bit in the CR to be used as a source.

**BC (21:25)**
Field used to specify a bit in the CR to be used as a source.

**BD (16:29)**
Immediate field used to specify a 14-bit signed two's complement branch displacement which is concatenated on the right with 0b00 and sign-extended to 64 bits.

**BF (6:8)**
Field used to specify one of the CR fields or one of the FPSCR fields to be used as a target.

**BFA (11:13 or 29:31)**
Field used to specify one of the CR fields or one of the FPSCR fields to be used as a source.

**BH (19:20)**
Field used to specify a hint in the Branch Conditional to Link Register and Branch Conditional to Count Register instructions. The encoding is described in Section 2.5, “Branch Instructions”.

**BI (11:15)**
Field used to specify a bit in the CR to be tested by a Branch Conditional instruction.

**BO (6:10)**
Field used to specify options for the Branch Conditional instructions. The encoding is described in Section 2.5, “Branch Instructions”.

**BT (6:10)**
Field used to specify a bit in the CR or in the FPSCR to be used as a target.

**BX (30) & B(16:20)**
Fields that are concatenated to specify a VSR to be used as a source.

**CT (7:10)**
Field used in X-form instructions to specify a cache target (see Section 4.3.2 of Book II).

**CX (28) & C(21:25)**
Fields that are concatenated to specify a VSR to be used as a source.

**D (16:31)**
Immediate field used to specify a 16-bit signed two's complement integer which is sign-extended to 64 bits.

**DCM (16:21)**
Immediate field used as the Data Class Mask.

**DCR (11:20)**
Field used by the Move To/From Device Control Register instructions (see Book III-E).

**DGM (16:21)**
Immediate field used as the Data Group Mask.

**DM (24:25)**
Immediate field used by *xxpermdi* instruction as doubleword permute control.

**DQ (16:27)**
Immediate field used to specify a 12-bit signed two’s complement integer which is concatenated on the right with 0b0000 and sign-extended to 64 bits.

**DS (16:29)**
Immediate field used to specify a 14-bit signed two’s complement integer which is concatenated on the right with 0b00 and sign-extended to 64 bits.

**DUI (6:10)**
Field used by the *dnh* instruction (see Book III-E).

**DUIS (11:20)**
Field used by the *dnh* instruction (see Book III-E).

**E (16)**
Field used by the Write MSR External Enable instruction (see Book III-E).

**E (12:15)**
Field used to specify the access types ordered by an Elemental Memory Barrier type of *sync* instruction.

**EH (31)**
Field used to specify a hint in the Load and Reserve instructions. The meaning is described in Section 4.4.2, “Load and Reserve and Store Conditional Instructions”, in Book II.

**FLM (7:14)**
Field mask used to identify the FPSCR fields that are to be updated by the *mttsf* instruction.

**FRA (11:15)**
Field used to specify an FPR to be used as a source.

**FRAp (11:15)**
Field used to specify an even/odd pair of FPRs to be concatenated and used as a source.

**FRB (16:20)**
Field used to specify an FPR to be used as a source.

**FRBp (16:20)**
Field used to specify an even/odd pair of FPRs to be concatenated and used as a source.

**FRC (21:25)**
Field used to specify an FPR to be used as a source.

**FRS (6:10)**
Field used to specify an FPR to be used as a source.

FRSp (6:10)
Field used to specify an even/odd pair of FPRs to be concatenated and used as a source.

FRT (6:10)
Field used to specify an FPR to be used as a target.

FRTp (6:10)
Field used to specify an even/odd pair of FPRs to be concatenated and used as a target.

FXM (12:19)
Field mask used to identify the CR fields that are to be written by the mtcfr and mtocfr instructions, or read by the mtocfr instruction.

IH (8:10)
Field used to specify a hint in the SLB Invalidate All instruction. The meaning is described in Section 5.9.3.1, "SLB Management Instructions", in Book III-S.

L (6)
Field used to specify whether the mtsfsf instruction updates the entire FPSCR.

L (10 or 15)
Field used to specify whether a fixed-point Compare instruction is to compare 64-bit numbers or 32-bit numbers.

Field used by the Data Cache Block Flush instruction (see Section 4.3.2 of Book II).

Field used by the Move To Machine State Register and TLB Invalidate Entry instructions (see Book III).

L (9:10)
Field used by the Data Cache Block Flush instruction (see Section 4.3.2 of Book II) and also by the Synchronize instruction (see Section 4.4.3 of Book II).

LEV (20:26)
Field used by the System Call instruction.

LI (6:29)
Immediate field used to specify a 24-bit signed two’s complement integer which is concatenated on the right with 0b00 and sign-extended to 64 bits.

LK (31)
LINK bit.
0 Do not set the Link Register.
1 Set the Link Register. The address of the instruction following the Branch instruction is placed into the Link Register.

MB (21:25) and ME (26:30)
Fields used in M-form instructions to specify a 64-bit mask consisting of 1-bits from bit MB+32 through bit ME+32 inclusive and 0-bits elsewhere, as described in Section 3.3.14, “Fixed-Point Rotate and Shift Instructions” on page 91.

MB (21:26)
Field used in MD-form and MDS-form instructions to specify the first 1-bit of a 64-bit mask, as described in Section 3.3.14, “Fixed-Point Rotate and Shift Instructions” on page 91.

ME (21:26)
Field used in MD-form and MDS-form instructions to specify the last 1-bit of a 64-bit mask, as described in Section 3.3.14, “Fixed-Point Rotate and Shift Instructions” on page 91.

MO (6:10)
Field used in X-form instructions to specify a subset of storage accesses.

NB (16:20)
Field used to specify the number of bytes to move in an immediate Move Assist instruction.

OC (6:20)
Field used by the Embedded Hypervisor Privilege instruction.

OPCD (0:5)
Primary opcode field.

OE (21)
Field used by XO-form instructions to enable setting OV and SO in the XER.

PMRN (11:20)
Field used to specify a Performance Monitor Register for the mfpmr and mtpmr instructions.

R (10)
Field used by the tbegin instruction to specify the start of a ROT.

R (15)
Immediate field that specifies whether the RMC is specifying the primary or secondary encoding.

RA (11:15)
Field used to specify a GPR to be used as a source or as a target.

RB (16:20)
Field used to specify a GPR to be used as a source.

Rc (21 OR 31)
RECORD bit.
0 Do not alter the Condition Register.
1 Set Condition Register Field 0, Field 1, or Field 6 as described in Section 2.3.1, “Condition Register” on page 30.

**RMC (21:22)**
Immediate field used for DFP rounding mode control.

**RS (6:10)**
Field used to specify a GPR to be used as a source.

**RSp (6:10)**
Field used to specify an even/odd pair of GPRs to be concatenated and used as a source.

**RT (6:10)**
Field used to specify a GPR to be used as a target.

**RTp (6:10)**
Field used to specify an even/odd pair of GPRs to be concatenated and used as a target.

**S (11 or 20)**
Immediate field that specifies signed versus unsigned conversion. Immediate field that specifies whether or not the rfebb instruction re-enables event-based branches.

**SH (16:20, or 16:20 and 30, or 16:21)**
Field used to specify a shift amount.

**SHB (22:25)**
Field used to specify a shift amount in bytes.

**SHW (24:25)**
Field used to specify a shift amount in words.

**SI (16:31 or 11:15)**
Immediate field used to specify a 16-bit signed integer.

**SIM (11:15)**
Immediate field used to specify a 5-bit signed integer.

**SP (11:12)**
Immediate field that specifies signed versus unsigned conversion.

**SPR (11:20)**
Field used to specify a Special Purpose Register for the mtsp and mfspr instructions.

**SR (12:15)**
Field used by the Segment Register Manipulation instructions (see Book III-S).

**SX (31) & S(6:10)**
Fields that are concatenated to specify a VSR to be used as a source.

Field used to specify the type of invalidation done by a TLB Invalidate Local instruction (see Book III-E).

**TBR (11:20)**
Field used by the Move From Time Base instruction (see Section 6.2.1 of Book II).

**TE (11:15)**
Immediate field that specifies a DFP exponent.

**TH (6:10)**
Field used by the data stream variant of the dcbt and dcbtsi instructions (see Section 4.3.2 of Book II).

**TO (6:10)**
Field used to specify the conditions on which to trap. The encoding is described in Section 3.3.11, “Fixed-Point Trap Instructions” on page 80.

**TX (31) & T (6:10)**
Fields that are concatenated to specify a VSR to be used as a target.

**U (16:19)**
Immediate field used as the data to be placed into a field in the FPSCR.

**UI (11:15, 16:20, or 16:31)**
Immediate field used to specify an unsigned integer.

**UIM (11:15, 12:15, 13:15, 14:15)**
Immediate field used to specify an unsigned integer.

**VRA (11:15)**
Field used to specify a VR to be used as a source.

**VRB (16:20)**
Field used to specify a VR to be used as a source.

**VRC (21:25)**
Field used to specify a VR to be used as a source.

**VRS (6:10)**
Field used to specify a VR to be used as a source.

**VRT (6:10)**
Field used to specify a VR to be used as a target.

**W (15)**
Field used by the mtfsi and mtfs instructions to specify the target word in the FPSCR.

**WC (9:10)**
Field used to specify the condition or conditions that cause instruction execution to resume after executing a wait [Category: Wait] instruction (see Section 4.4.4 of Book II).
1.7 Classes of Instructions

An instruction falls into exactly one of the following three classes:

- Defined
- Illegal
- Reserved

The class is determined by examining the opcode, and the extended opcode if any. If the opcode, or combination of opcode and extended opcode, is not that of a defined instruction or a reserved instruction, the instruction is illegal.

1.7.1 Defined Instruction Class

This class of instructions contains all the instructions defined in this document.

A defined instruction can have preferred and/or invalid forms, as described in Section 1.8.1, “Preferred Instruction Forms” and Section 1.8.2, “Invalid Instruction Forms”. Instructions that are part of a category that is not supported are treated as illegal instructions.

1.7.2 Illegal Instruction Class

This class of instructions contains the set of instructions described in Appendix D of Book Appendices. Illegal instructions are available for future extensions of the Power ISA; that is, some future version of the Power ISA may define any of these instructions to perform new functions.

Any attempt to execute an illegal instruction will cause the system illegal instruction error handler to be invoked and will have no other effect.

An instruction consisting entirely of binary 0s is guaranteed always to be an illegal instruction. This increases the probability that an attempt to execute data or uninitialized storage will result in the invocation of the system illegal instruction error handler.

1.7.3 Reserved Instruction Class

This class of instructions contains the set of instructions described in Appendix E of Book Appendices.

Reserved instructions are allocated to specific purposes that are outside the scope of the Power ISA.

Any attempt to execute a reserved instruction will:

- perform the actions described by the implementation if the instruction is implemented; or
- cause the system illegal instruction error handler to be invoked if the instruction is not implemented.
1.8 Forms of Defined Instructions

1.8.1 Preferred Instruction Forms

Some of the defined instructions have preferred forms. For such an instruction, the preferred form will execute in an efficient manner, but any other form may take significantly longer to execute than the preferred form. Instructions having preferred forms are:

- the Condition Register Logical instructions
- the Load/Store Multiple instructions
- the Load/Store String instructions
- the Or Immediate instruction (preferred form of no-op)
- the Move To Condition Register Fields instruction

1.8.2 Invalid Instruction Forms

Some of the defined instructions can be coded in a form that is invalid. An instruction form is invalid if one or more fields of the instruction, excluding the opcode field(s), are coded incorrectly in a manner that can be deduced by examining only the instruction encoding.

In general, any attempt to execute an invalid form of an instruction will either cause the system illegal instruction error handler to be invoked or yield boundedly undefined results. Exceptions to this rule are stated in the instruction descriptions.

Some instruction forms are invalid because the instruction contains a reserved value in a defined field (see Section 1.3.3 on page 5); these invalid forms are not discussed further. All other invalid forms are identified in the instruction descriptions.

References to instructions elsewhere in this document assume the instruction form is not invalid, unless otherwise stated or obvious from context.

Assembler Note

Assemblers should report uses of invalid instruction forms as errors.

1.8.3 Reserved-no-op Instructions

[Category: Phased-In]

Reserved-no-op instructions include the following extended opcodes under primary opcode 31: 530, 562, 594, 626, 658, 690, 722, and 754.

Reserved-no-op instructions are provided in the architecture to anticipate the eventual adoption of performance hint instructions to the architecture. For these instructions, which cause no visible change to architected state, employing a reserved-no-op opcode will allow software to use this new capability on new implementations that support it while remaining compatible with existing implementations that may not support the new function.

When a reserved-no-op instruction is executed, no operation is performed.

Reserved-no-op instructions are not assigned instruction names or mnemonics. There are no individual descriptions of reserved-no-op instructions in this document.

1.9 Exceptions

There are two kinds of exception, those caused directly by the execution of an instruction and those caused by an asynchronous event. In either case, the exception may cause one of several components of the system software to be invoked.

The exceptions that can be caused directly by the execution of an instruction include the following:

- an attempt to execute an illegal instruction, or an attempt by an application program to execute a “privileged” instruction (see Book III) (system illegal instruction error handler or system privileged instruction error handler)
- the execution of a defined instruction using an invalid form (system illegal instruction error handler or system privileged instruction error handler)
- an attempt to execute an instruction that is not provided by the implementation (system illegal instruction error handler)
- an attempt to access a storage location that is unavailable (system instruction storage error handler or system data storage error handler)
- an attempt to access storage with an effective address alignment that is invalid for the instruction (system alignment error handler)
- the execution of a System Call instruction (system service program)
- the execution of a Trap instruction that traps (system trap handler)
- the execution of a floating-point instruction that causes a floating-point enabled exception to exist (system floating-point enabled exception error handler)
- the execution of an auxiliary processor instruction that causes an auxiliary processor enabled exception to exist (system auxiliary processor enabled exception error handler)

The exceptions that can be caused by an asynchronous event are described in Book III.
The invocation of the system error handler is precise, except that the invocation of the auxiliary processor enabled exception error handler may be imprecise, and if one of the imprecise modes for invoking the system floating-point enabled exception error handler is in effect (see page 125), then the invocation of the system floating-point enabled exception error handler may also be imprecise. When the system error handler is invoked imprecisely, the excepting instruction does not appear to complete before the next instruction starts (because one of the effects of the excepting instruction, namely the invocation of the system error handler, has not yet occurred).

Additional information about exception handling can be found in Book III.

### 1.10 Storage Addressing

A program references storage using the effective address computed by the processor when it executes a Storage Access or Branch instruction (or certain other instructions described in Book II and Book III), or when it fetches the next sequential instruction.

Bytes in storage are numbered consecutively starting with 0. Each number is the address of the corresponding byte.

The byte ordering (Big-Endian or Little-Endian) for a storage access is specified by the operating system. In the Embedded environment this ordering is a page attribute (see Book II) and is specified independently for each virtual page, while in the Server environment it is specified by the two mode bits, LE and SLE (see Book III-S), and applies to all storage.

#### 1.10.1 Storage Operands

A storage operand may be a byte, a halfword, a word, a doubleword, or a quadword, or, for the Load/Store Multiple and Move Assist instructions, a sequence of bytes (Move Assist) or words (Load/Store Multiple). For example, the storage operand of a Load Floating-Point Double Pair instruction is a quadword, not two double-words. The address of a storage operand is the address of its first byte (i.e., of its lowest-numbered byte). An instruction for which the storage operand is a byte is said to cause a byte access, and similarly for halfword, word, doubleword, and quadword.

Operand length is implicit for each instruction.

The storage operand of a single-register Storage Access instruction or quadword Load or Store instruction has a “natural” alignment boundary equal to the operand length. In other words, the “natural” address of such an operand is an integral multiple of the operand length. Such an operand is said to be aligned if it is aligned at its natural boundary; otherwise it is said to be unaligned. See the following table.

<table>
<thead>
<tr>
<th>Operand</th>
<th>Length</th>
<th>Addr60:63 if aligned</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte</td>
<td>8 bits</td>
<td>xxxxx</td>
</tr>
<tr>
<td>Halfword</td>
<td>2 bytes</td>
<td>xxx0</td>
</tr>
<tr>
<td>Word</td>
<td>4 bytes</td>
<td>xx00</td>
</tr>
<tr>
<td>Doubleword</td>
<td>8 bytes</td>
<td>x000</td>
</tr>
<tr>
<td>Quadword</td>
<td>16 bytes</td>
<td>0000</td>
</tr>
</tbody>
</table>

Note: An “x” in an address bit position indicates that the bit can be 0 or 1 independent of the contents of other bits in the address.

The concept of alignment is also applied more generally, to any datum in storage. For example, a 12-byte datum in storage is said to be word-aligned if its address is an integral multiple of 4.

Some instructions require their storage operands to have certain alignments. In addition, alignment may affect performance. For single-register Storage Access instructions and quadword Load and Store instructions, the best performance is obtained when storage operands are aligned. Additional effects of data placement on performance are described in Chapter 2 of Book II.

When a storage operand of length N bytes starting at effective address EA is copied between storage and a register that is R bytes long (i.e., the register contains bytes numbered from 0, most significant, through R-1, least significant), the bytes of the operand are placed into the register or into storage in a manner that depends on the byte ordering for the storage access as shown in Figure 31, unless otherwise specified in the instruction description.

<table>
<thead>
<tr>
<th>Big-Endian Byte Ordering</th>
<th>Little-Endian Byte Ordering</th>
</tr>
</thead>
<tbody>
<tr>
<td>Load</td>
<td>Store</td>
</tr>
<tr>
<td>for i=0 to N-1:</td>
<td>for i=0 to N-1:</td>
</tr>
<tr>
<td>RT<a href="R-N">RS</a>+i&lt;-MEM(EA+i,1)</td>
<td>MEM(EA+i,1)&lt;-(RS)[R-N]</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Load</td>
<td>Store</td>
</tr>
<tr>
<td>for i=0 to N-1:</td>
<td>for i=0 to N-1:</td>
</tr>
<tr>
<td>RT<a href="R-1">RS</a>+i&lt;-MEM(EA+i,1)</td>
<td>MEM(EA+i,1)&lt;-(RS)[R-1]</td>
</tr>
</tbody>
</table>

Notes:
1. In this table, subscripts refer to bytes in a register rather than to bits as defined in Section 1.3.2.
2. This table does not apply to the **lvebx**, **lvehx**, **lvewx, stvebx, stvehx**, and **stvewx** instructions.

**Figure 31. Storage operands and byte ordering**

Figure 32 shows an example of a C language structure **s** containing an assortment of scalars and one character string. The value assumed to be in each structure element is shown in hex in the C comments; these values are used below to show how the bytes making up each structure element are mapped into storage. It is assumed that structure s is compiled for
32-bit mode or for a 32-bit implementation. (This affects the length of the pointer to c.)

C structure mapping rules permit the use of padding (skipped bytes) in order to align the scalars on desirable boundaries. Figures 33 and 34 show each scalar aligned at its natural boundary. This alignment introduces padding of four bytes between a and b, one byte between d and e, and two bytes between e and f. The same amount of padding is present for both Big-Endian and Little-Endian mappings.

The Big-Endian mapping of structure s is shown in Figure 33. Addresses are shown in hex at the left of each doubleword, and in small figures below each byte. The contents of each byte, as indicated in the C example in Figure 32, are shown in hex (as characters for the elements of the string).

The Little-Endian mapping of structure s is shown in Figure 34. Doublewords are shown laid out from right to left, which is the common way of showing storage maps for processors that implement only Little-Endian byte ordering.

The Big-Endian mapping of program p is shown in Figure 37 (assuming the program starts at address 0).

struct {
  int a; /* 0x1112_1314 */
  double b; /* 0x2122_2324_2526_2728 */
  char * c; /* 0x3132_3334 */
  char d[7]; /* 'A', 'B', 'C', 'D', 'E', 'F', 'G' */
  short e; /* 0x5152 */
  int f; /* 0x6162_6364 */
} s;

Figure 34. Little-Endian mapping of structure ‘s’
Figure 37. Big-Endian mapping of program ‘p’

The Little-Endian mapping of program p is shown in Figure 38.

Figure 38. Little-Endian mapping of program ‘p’
Programming Note

The terms Big-Endian and Little-Endian come from Part I, Chapter 4, of Jonathan Swift's Gulliver's Travels. Here is the complete passage, from the edition printed in 1734 by George Faulkner in Dublin.

... our Histories of six Thousand Moons make no Mention of any other Regions, than the two great Empires of Lilliput and Blefuscu. Which two mighty Powers have, as I was going to tell you, been engaged in a most obstinate War for six and thirty Moons past. It began upon the following Occasion. It is allowed on all Hands, that the primitive Way of breaking Eggs before we eat them, was upon the larger End: But his present Majesty's Grand-father, while he was a Boy, going to eat an Egg, and breaking it according to the ancient Practice, happened to cut one of his Fingers. Whereupon the Emperor his Father, published an Edict, commanding all his Subjects, upon great Penalties, to break the smaller End of their Eggs. The People so highly resented this Law, that our Histories tell us, there have been six Rebellions raised on that Account; wherein one Emperor lost his Life, and another his Crown. These civil Commotions were constantly fomented by the Monarchs of Blefuscu; and when they were quelled, the Exiles always fled for Refuge to that Empire. It is computed that eleven Thousand Persons have, at several Times, suffered Death, rather than submit to break their Eggs at the smaller End. Many hundred large Volumes have been published upon this Controversy: But the Books of the Big-Endians have been long forbidden, and the whole Party rendered incapable by Law of holding Employments. During the Course of these Troubles, the Emperors of Blefuscu did frequently expostulate by their Ambassadors, accusing us of making a Schism in Religion, by offending against a fundamental Doctrine of our great Prophet Lustrog, in the fifty-fourth Chapter of the Brundrecal, (which is their Alcoran.) This, however, is thought to be a mere Strain upon the text: For the Words are these; That all true Believers shall break their Eggs at the convenient End: and which is the convenient End, seems, in my humble Opinion, to be left to every Man's Conscience, or at least in the Power of the chief Magistrate to determine. Now the Big-Endian Exiles have found so much Credit in the Emperor of Blefuscu's Court; and so much private Assistance and Encouragement from their Party here at home, that a bloody War has been carried on between the two Empires for six and thirty Moons with various Success; during which Time we have lost Forty Capital Ships, and a much greater Number of smaller Vessels, together with thirty thousand of our best Seamen and Soldiers; and the Damage received by the Enemy is reckoned to be somewhat greater than ours. However, they have now equipped a numerous Fleet, and are just preparing to make a Descent upon us: and his Imperial Majesty, placing great Confidence in your Valour and Strength, hath commanded me to lay this Account of his Affairs before you.

1.10.3 Effective Address Calculation

An effective address is computed by the processor when executing a Storage Access or Branch instruction (or certain other instructions described in Book II, Book III, and Book VLE) when fetching the next sequential instruction, or when invoking a system error handler. The following provides an overview of this process. More detail is provided in the individual instruction descriptions.

Effective address calculations, for both data and instruction accesses, use 64-bit two's complement addition. All 64 bits of each address component participate in the calculation regardless of mode (32-bit or 64-bit). In this computation one operand is an address (which is by definition an unsigned number) and the second is a signed offset. Carries out of the most significant bit are ignored.

In 64-bit mode, the entire 64-bit result comprises the 64-bit effective address. The effective address arithmetic wraps around from the maximum address, 2^{64} - 1, to address 0, except that if the current instruction is at effective address 2^{64} - 4 the effective address of the next sequential instruction is undefined.

In 32-bit mode, the low-order 32 bits of the 64-bit result, preceded by 32 0 bits, comprise the 64-bit effective address for the purpose of addressing storage. When an effective address is placed into a register by an instruction or event, the value placed into the high-order 32 bits of the register differs between the Server environment and the Embedded environment.

- Server environment, and Embedded Environment when the high-order 32 bits of GPRs are implemented:
  - Load with Update and Store with Update instructions set the high-order 32 bits of register RA to the high-order 32 bits of the 64-bit result.
- In all other cases (e.g., the Link Register when set by Branch instructions having \( LK=1 \), Special Purpose Registers when set to an effective address by invocation of a system error handler) the high-order 32 bits of the register are set to 0s except as described in the last sentence of this paragraph.

- Embedded environment when the high-order 32 bits of GPRs are not implemented for the following cases:
  The high-order 32 bits of the register are set to an undefined value except for the Initialize Next Instruction register [Category: Embedded.Multi-threading] (see Section 1.5.2 and Book III), and for the following case. For a register that is loaded with an effective address by the invocation of a system error handler, the high-order 32 bits of the register are set to 0s if the computation mode is 64-bit after the system error is invoked. The 64-bit current instruction address is not affected by a change from 32-bit mode to 64-bit mode, but is affected by a change from 64-bit mode to 32-bit mode. In the latter case, the high-order 32 bits are set to 0. The same is true for the 64-bit next instruction address, except as described in the last item of the list below.

As used to address storage, the effective address arithmetic appears to wrap around from the maximum address, \( 2^{32} - 1 \), to address 0, except that if the current instruction is at effective address \( 2^{32} - 4 \) the effective address of the next sequential instruction is undefined.

RA is a field in the instruction which specifies an address component in the computation of an effective address. A zero in the RA field indicates the absence of the corresponding address component. A value of zero is substituted for the absent component of the effective address computation. This substitution is shown in the instruction descriptions as (RA|0).

Effective addresses are computed as follows. In the descriptions below, it should be understood that “the contents of a GPR” refers to the entire 64-bit contents, independent of mode, but that in 32-bit mode only bits 32:63 of the 64-bit result of the computation are used to address storage.

- With X-form instructions, in computing the effective address of a data element, the contents of the GPR designated by RB (or the value zero for `lswi` and `stswi`) are added to the contents of the GPR designated by RA or to zero if RA=0 or RA is not used in forming the EA.

- With D-form instructions, the 16-bit D field is sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0.

- With DS-form instructions, the 14-bit DS field is concatenated on the right with 0b00 and sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0.

- With I-form Branch instructions, the 24-bit LI field is concatenated on the right with 0b00 and sign-extended to form a 64-bit address component. If AA=0, this address component is added to the address of the Branch instruction to form the effective address of the target instruction. If AA=1, this address component is the effective address of the target instruction.

- With B-form Branch instructions, the 14-bit BD field is concatenated on the right with 0b00 and sign-extended to form a 64-bit address component. If AA=0, this address component is added to the address of the Branch instruction to form the effective address of the target instruction. If AA=1, this address component is the effective address of the target instruction.

- With XL-form Branch instructions, bits 0:61 of the Link Register or the Count Register are concatenated on the right with 0b00 to form the effective address of the target instruction.

- With sequential instruction fetching, the value 4 is added to the address of the current instruction to form the effective address of the next instruction, except that if the current instruction is at the maximum instruction effective address for the mode (\( 2^{64} - 4 \) in 64-bit mode, \( 2^{32} - 4 \) in 32-bit mode) the effective address of the next sequential instruction is undefined. (There is one other exception to this rule; this exception involves changing between 32-bit mode and 64-bit mode and is described in Section 6.3.2 of Book III-E and Section 6.3.2 of Book III-E.)

If the size of the operand of a storage access instruction is more than one byte, the effective address for each byte after the first is computed by adding 1 to the effective address of the preceding byte.
Chapter 2. Branch Facility

2.1 Branch Facility Overview

This chapter describes the registers and instructions that make up the Branch Facility.

2.2 Instruction Execution Order

In general, instructions appear to execute sequentially, in the order in which they appear in storage. The exceptions to this rule are listed below.

- **Branch** instructions for which the branch is taken cause execution to continue at the target address specified by the Branch instruction.
- **Trap** instructions for which the trap conditions are satisfied, and **System Call** instructions, cause the appropriate system handler to be invoked.
- Transaction failure will eventually cause the transaction’s failure handler, implied by the `tbegin` instruction, to be invoked. See the programming note following the `tbegin` description in Section 5.5 of Book II.
- Exceptions can cause the system error handler to be invoked, as described in Section 1.9, “Exceptions” on page 22.
- Returning from a system service program, system trap handler, or system error handler causes execution to continue at a specified address.

The model of program execution in which the processor appears to execute one instruction at a time, completing each instruction before beginning to execute the next instruction is called the “sequential execution model.” In general, the processor obeys the sequential execution model. For the instructions and facilities defined in this Book, the only exceptions to this rule are the following.

- A floating-point exception occurs when the processor is running in one of the Imprecise floating-point exception modes (see Section 4.4). The instruction that causes the exception need not complete before the next instruction begins execution, with respect to setting exception bits and (if the exception is enabled) invoking the system error handler.

- A Store instruction modifies one or more bytes in an area of storage that contains instructions that will subsequently be executed. Before an instruction in that area of storage is executed, software synchronization is required to ensure that the instructions executed are consistent with the results produced by the Store instruction.

---

**Programming Note**

This software synchronization will generally be provided by system library programs (see Section 1.9 of Book II). Application programs should call the appropriate system library program before attempting to execute modified instructions.
2.3 Branch Facility Registers

2.3.1 Condition Register

The Condition Register (CR) is a 32-bit register which reflects the result of certain operations, and provides a mechanism for testing (and branching).

Figure 39. Condition Register

The bits in the Condition Register are grouped into eight 4-bit fields, named CR Field 0 (CR0), ..., CR Field 7 (CR7), which are set in one of the following ways.

- Specified fields of the CR can be set by a move to the CR from a GPR (mtcrf, mtocrf).
- A specified field of the CR can be set by a move to the CR from another CR field (mcrf), from XER32:35 (mcxr), or from the FPSCR (mcrfs).
- CR Field 0 can be set as the implicit result of a fixed-point instruction.
- CR Field 1 can be set as the implicit result of a floating-point instruction.
- CR Field 1 can be set as the implicit result of a decimal floating-point instruction.
- CR Field 6 can be set as the implicit result of a vector instruction.
- A specified CR field can be set as the result of a Compare instruction or of a tcheck instruction (see Book II).

Instructions are provided to perform logical operations on individual CR bits and to test individual CR bits.

For all fixed-point instructions in which Rc=1, and for addic, andi, and andis., the first three bits of CR Field 0 (bits 32:34 of the Condition Register) are set by signed comparison of the result to zero, and the fourth bit of CR Field 0 (bit 35 of the Condition Register) is copied from the SO field of the XER. “Result” here refers to the entire 64-bit value placed into the target register in 64-bit mode, and to bits 32:63 of the 64-bit value placed into the target register in 32-bit mode.

```lisp
if (64-bit mode)
    then M = 0
else M = 32
if (target_register)M,63 < 0 then c ← 0b100
else if (target_register)M,63 > 0 then c ← 0b010
else
    c ← 0b001
CR0 ← c || XERSO
```

If any portion of the result is undefined, then the value placed into the first three bits of CR Field 0 is undefined.

The bits of CR Field 0 are interpreted as follows.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><strong>Negative</strong> (LT)</td>
</tr>
<tr>
<td></td>
<td>The result is negative.</td>
</tr>
<tr>
<td>1</td>
<td><strong>Positive</strong> (GT)</td>
</tr>
<tr>
<td></td>
<td>The result is positive.</td>
</tr>
<tr>
<td>2</td>
<td><strong>Zero</strong> (EQ)</td>
</tr>
<tr>
<td></td>
<td>The result is zero.</td>
</tr>
<tr>
<td>3</td>
<td><strong>Summary Overflow</strong> (SO)</td>
</tr>
<tr>
<td></td>
<td>This is a copy of the contents of XER_SO at the completion of the instruction.</td>
</tr>
</tbody>
</table>

With the exception of tcheck, the Transactional Memory instructions set CR0[2] indicating the state of the facility prior to instruction execution, or transaction failure. A complete description of the meaning of these bits is given in the instruction descriptions in Section 5.5 of Book II. These bits are interpreted as follows:

<table>
<thead>
<tr>
<th>CR0</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>000 0</td>
<td>Transaction state of Non-transactional prior to instruction</td>
</tr>
<tr>
<td>010 0</td>
<td>Transaction state of Transactional prior to instruction</td>
</tr>
<tr>
<td>001 0</td>
<td>Transaction state of Suspended prior to instruction</td>
</tr>
<tr>
<td>101 0</td>
<td>Transaction failure</td>
</tr>
</tbody>
</table>

The tcheck instruction similarly sets bits 1 and 2 of CR field BF to indicate the transaction state, and additionally sets bit 0 to TDOOMED, as defined in Section 5.5 of Book II.

<table>
<thead>
<tr>
<th>CR field BF</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TDOOMED 0 0</td>
<td>Transaction state of Non-transactional prior to instruction</td>
</tr>
<tr>
<td>TDOOMED 1 0</td>
<td>Transaction state of Transactional prior to instruction</td>
</tr>
<tr>
<td>TDOOMED 0 1</td>
<td>Transaction state of Suspended prior to instruction</td>
</tr>
</tbody>
</table>

**Programming Note**

Setting of bit 3 of the specified CR field to zero by tcheck and of field CR0[3] to zero by other TM instructions is intended to preserve these bits for future function. Software should not depend on the bits being zero.

The stbcx., sthcx., stwcx., stdcx., and stqcx. instructions (see Section 4.4.2, “Load and Reserve and Store Operations”...
For all floating-point instructions in which Rc=1, CR Field 0.

Conditional Instructions”, in Book II) also set CR Field 0.

For all floating-point instructions in which Rc=1, CR Field 1 (bits 36:39 of the Condition Register) is set to the Floating-Point exception status, copied from bits 0:3 of the Floating-Point Status and Control Register. This occurs regardless of whether any exceptions are enabled, and regardless of whether the writing of the result is suppressed (see Section 4.4, “Floating-Point Exceptions” on page 124). These bits are interpreted as follows.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>Floating-Point Exception Summary (FX)</td>
</tr>
<tr>
<td>33</td>
<td>Floating-Point Enabled Exception Summary (FEX)</td>
</tr>
<tr>
<td>34</td>
<td>Floating-Point Invalid Operation Exception Summary (VX)</td>
</tr>
<tr>
<td>35</td>
<td>Floating-Point Overflow Exception (OX)</td>
</tr>
</tbody>
</table>

For Compare instructions, a specified CR field is set to reflect the result of the comparison. The bits of the specified CR field are interpreted as follows. A complete description of how the bits are set is given in the instruction descriptions in Section 3.3.10, “Fixed-Point Compare Instructions” on page 78, Section 4.6.8, “Floating-Point Compare Instructions” on page 159, and Section 8.3.9, “SPE Instruction Set” on page 594.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Less Than, Floating-Point Less Than (LT, FL)</td>
</tr>
<tr>
<td>1</td>
<td>Greater Than, Floating-Point Greater Than (GT, FG)</td>
</tr>
<tr>
<td>2</td>
<td>Equal, Floating-Point Equal (EQ, FE)</td>
</tr>
</tbody>
</table>

For fixed-point Compare instructions, this is a copy of the contents of XERSO at the completion of the instruction. For floating-point Compare instructions, one or both of (FRA) and (FRB) is a NaN.

The Vector Integer Compare instructions (see Section 5.9.2, “Vector Integer Compare Instructions”) compare two Vector Registers element by element, interpreting the elements as unsigned or signed integers depending on the instruction, and set the corresponding element of the target Vector Register to all 1s if the relation being tested is true and 0s if the relation being tested is false.

If Rc=1, CR Field 6 is set to reflect the result of the comparison, as follows.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The relation is true for all element pairs (i.e., VRT is set to all 1s).</td>
</tr>
<tr>
<td>1</td>
<td>The relation is false for all element pairs (i.e., VRT is set to all 0s).</td>
</tr>
</tbody>
</table>

The Vector Floating-Point Compare instructions compare two Vector Registers word element by word element, interpreting the elements as single-precision floating-point numbers. With the exception of the Vector Compare Bounds Floating-Point instruction, they set the target Vector Register, and CR Field 6 if Rc=1, in the same manner as do the Vector Integer Compare instructions.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The relation is true for all element pairs (i.e., VRT is set to all 1s).</td>
</tr>
<tr>
<td>1</td>
<td>The relation is false for all element pairs (i.e., VRT is set to all 0s).</td>
</tr>
</tbody>
</table>

The Vector Compare Bounds Floating-Point instruction on page 251 sets CR Field 6 if Rc=1, to indicate whether the elements in VRA are within the bounds specified by the corresponding element in VRB, as explained in the instruction description. A single-precision floating-point value x is said to be “within the bounds” specified by a single-precision floating-point value y if -y ≤ x ≤ y.
2. Set to indicate whether all four elements in VRA are within the bounds specified by the corresponding element in VRB, otherwise set to 0.

2.3.2 Link Register

The Link Register (LR) is a 64-bit register. It can be used to provide the branch target address for the Branch Conditional to Link Register instruction, and it holds the return address after Branch instructions for which \( LK=1 \).

<table>
<thead>
<tr>
<th>LR</th>
<th>63</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Figure 40. Link Register

2.3.3 Count Register

The Count Register (CTR) is a 64-bit register. It can be used to hold a loop count that can be decremented during execution of Branch instructions that contain an appropriately coded BO field. If the value in the Count Register is 0 before being decremented, it is \(-1\) afterward. The Count Register can also be used to provide the branch target address for the Branch Conditional to Count Register instruction.

<table>
<thead>
<tr>
<th>CTR</th>
<th>63</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Figure 41. Count Register

2.3.4 Target Address Register

The Target Address Register (TAR) is a 64-bit register. It can be used to provide bits 0:61 of the branch target address for the Branch Conditional to Branch Target Address Register instruction. Bits 62:63 are ignored by the hardware but can be set and reset by software.

<table>
<thead>
<tr>
<th>Effective Address</th>
<th>62</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Figure 42. Target Address Register

Programming Note

The TAR is reserved for system software.

2.4 Branch History Rolling Buffer [Category: Server]

The Branch History Rolling Buffer (BHRB) is a buffer containing an implementation-dependent number of entries, referred to as BHRB Entries (BHRBEs), that contain information related to branches that have been taken. Entries are numbered from 0 through \( n \), where \( n \) is implementation dependent. Entry 0 is the most-recently written entry.

The system program typically controls the availability of the BHRB as well as the number of entries that it contains. If the BHRB is accessed when it is unavailable, the Facility Unavailable error handler is invoked.

Various events or actions by the system program may result in the BHRB occasionally being cleared. If BHRB entries are read after this has occurred, 0s will be returned. See the description of the \texttt{mfbhrbe} instruction for additional information.

The BHRB is typically used in conjunction with Performance Monitor event-based branches. (See Chapter 7 of Book II.) When used in conjunction with this facility, BESC\textsubscript{RME} is set to 1 to enable Performance Monitor event-based branches, and Performance Monitor alerts are enabled to enable the writing of BHRB entries. (See Section 9.4.4 of Book III-S.) When a Performance Monitor alert occurs, Performance Monitor alerts are disabled, BHRB entries are no longer written, and an event-based branch occurs. (See Chapter 9 of Book III-S for additional information.) The event-based branch handler can then access the contents of the BHRB for analysis.

When the BHRB is written by hardware, only those Branch instructions that meet the filtering criterion are written. The filtering criterion is set by the system program. (See Section 9.4.7 of Book III-S.)

The following paragraphs describe the entries written into the BHRB for various types of Branch instructions for which the branch was taken. In some circumstances, however, the hardware may be unable to make the entry even though the following paragraphs require it. In such cases, the hardware sets the EA field to 0, and indicates any missed entries using the T and P fields. (See Section 2.4.1.)

When an I-form or B-form Branch instruction is entered into the BHRB, bits 0:61 of the branch instruction are written into the next available entry, except that the entry may or may not be written if the instruction following the Branch instruction is not another Branch instruction, and target address of the Branch instruction does not exceed its effective address by more than 8.

When a XL-form Branch instruction is entered into the BHRB, bits 0:61 of the effective address of the Branch instruction are placed into the next available entry, except that the entry may or may not be written if the instruction following the Branch instruction is another Branch instruction, and target address of the Branch instruction does not exceed its effective address by more than 8.

When a XL-form Branch instruction is entered into the BHRB, bits 0:61 of the branch instruction are written into the next available entry if allowed by the filtering mode; subsequently, bits 0:61 of the effective address of the Branch target is written into the following entry. The BHRB is read by means of the \texttt{mfbhrbe} instruction.

BHRB entries are written as described above without regard to transactional state and are not removed due to transaction failures.
2.4.1 Branch History Rolling Buffer Entry Format

Branch History Rolling Buffer Data Entries (BHRBEs) have the following format.

<table>
<thead>
<tr>
<th>Effective Address</th>
<th>T</th>
<th>P</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>62</td>
<td>63</td>
</tr>
</tbody>
</table>

Figure 43. Branch History Rolling Buffer Data

When this field is set to a non-zero value, it contains bits 0:61 of the effective address of the instruction indicated by the T field; otherwise this field indicates that the entry is a marker with the meaning specified by the T and P fields.

When the EA field contains a non-zero value, bits 62:63 have the following meanings.

62  **Target Address (T)**

- 0 The EA field contains bits 0:61 of the effective address of a Branch instruction for which the branch was taken.
- 1 The EA field contains bits 0:61 of the branch target effective address corresponding to an XL-form Branch instruction.

63  **Prediction (P)**

When T=0, this field has the following meaning.

- 0 The outcome of the Branch instruction was correctly predicted.
- 1 The outcome of the Branch instruction was mispredicted.

When T=1, this field has the following meaning.

- 0 The Branch instruction was predicted to be taken and the target address was predicted correctly, or the target address was not predicted because the Branch instruction was predicted to be not taken.
- 1 The target address was mispredicted.

When the EA field contains a zero value, either the entry is a marker or is an entry for a Branch instruction for which the instruction address or target address is 0.

It is expected that programs will not contain Branch instructions with instruction or target addresses equal to 0. If such instructions exist, however, markers become unusable because BHRB entries for various markers cannot be distinguished from entries for Branch instructions with instruction or target addresses equal to 0.

For Branch instructions with zero instruction or target addresses, the EA field is set to 0 and bits 62:63 are specified above. For Branch instructions with non-zero effective and target addresses, the EA field is set to 0 and bits 62:63 specify the type of marker as described below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>This entry is either not implemented or has been cleared, and there are no valid entries beyond the current entry.</td>
</tr>
<tr>
<td>01</td>
<td>A Branch instruction for which the branch was taken was executed, but the hardware was unable to enter its effective address and, for XL-Form Branch instructions, its target effective address.</td>
</tr>
<tr>
<td>10</td>
<td>Reserved</td>
</tr>
<tr>
<td>11</td>
<td>The previous entry contains bits 0:61 of the effective address of an XL-form Branch instruction for which the branch was taken, and the filtering mode required bits 0:61 of the current entry to indicate the effective address of the branch target, but the hardware was unable to enter the effective address of the branch target.</td>
</tr>
</tbody>
</table>
2.5 Branch Instructions

The sequence of instruction execution can be changed by the Branch instructions. Because all instructions are on word boundaries, bits 62 and 63 of the generated branch target address are ignored by the processor in performing the branch.

The Branch instructions compute the effective address (EA) of the target in one of the following five ways, as described in Section 1.10.3, “Effective Address Calculation” on page 26.

1. Adding a displacement to the address of the Branch instruction (Branch or Branch Conditional with AA=0).
2. Specifying an absolute address (Branch or Branch Conditional with AA=1).
3. Using the address contained in the Link Register (Branch Conditional to Link Register).
4. Using the address contained in the Count Register (Branch Conditional to Count Register).
5. Using the address contained in the Target Address Register (Branch Conditional to Target Address Register).

In all five cases, in 32-bit mode the final step in the address computation is setting the high-order 32 bits of the target address to 0.

For the first two methods, the target addresses can be computed sufficiently ahead of the Branch instruction that instructions can be prefetched along the target path. For the third through fifth methods, prefetching instructions along the target path is also possible provided the Link Register or the Count Register is loaded sufficiently ahead of the Branch instruction.

Branching can be conditional or unconditional, and the return address can optionally be provided. If the return address is to be provided (LK=1), the effective address of the instruction following the Branch instruction is placed into the Link Register after the branch target address has been computed; this is done regardless of whether the branch is taken.

For Branch Conditional instructions, the BO field specifies the conditions under which the branch is taken, as shown in Figure 44. In the figure, M=0 in 64-bit mode and M=32 in 32-bit mode.

<table>
<thead>
<tr>
<th>BO</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000z</td>
<td>Decrement the CTR, then branch if the decremented CTR_M:63≠0 and CR_Bi=0</td>
</tr>
<tr>
<td>0001z</td>
<td>Decrement the CTR, then branch if the decremented CTR_M:63=0 and CR_Bi=0</td>
</tr>
<tr>
<td>001at</td>
<td>Branch if CR_Bi=0</td>
</tr>
<tr>
<td>0100z</td>
<td>Decrement the CTR, then branch if the decremented CTR_M:63≠0 and CR_Bi=1</td>
</tr>
<tr>
<td>0101z</td>
<td>Decrement the CTR, then branch if the decremented CTR_M:63=0 and CR_Bi=1</td>
</tr>
<tr>
<td>011at</td>
<td>Branch if CR_Bi=1</td>
</tr>
<tr>
<td>1a00t</td>
<td>Decrement the CTR, then branch if the decremented CTR_M:63=0</td>
</tr>
<tr>
<td>1a01t</td>
<td>Decrement the CTR, then branch if the decremented CTR_M:63=0</td>
</tr>
<tr>
<td>1z1zz</td>
<td>Branch always</td>
</tr>
</tbody>
</table>

**Figure 44. BO field encodings**

The “a” and “t” bits of the BO field can be used by software to provide a hint about whether the branch is likely to be taken or is likely not to be taken, as shown in Figure 45.

<table>
<thead>
<tr>
<th>at</th>
<th>Hint</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No hint is given</td>
</tr>
<tr>
<td>01</td>
<td>Reserved</td>
</tr>
<tr>
<td>10</td>
<td>The branch is very likely not to be taken</td>
</tr>
<tr>
<td>11</td>
<td>The branch is very likely to be taken</td>
</tr>
</tbody>
</table>

**Figure 45. “at” bit encodings**

**Programming Note**

Many implementations have dynamic mechanisms for predicting whether a branch will be taken. Because the dynamic prediction is likely to be very accurate, and is likely to be overridden by any hint provided by the “at” bits, the “at” bits should be set to 0b00 unless the static prediction implied by at=0b10 or at=0b11 is highly likely to be correct.

For Branch Conditional to Link Register and Branch Conditional to Count Register instructions, the BH field...
provides a hint about the use of the instruction, as shown in Figure 46.

<table>
<thead>
<tr>
<th>BH</th>

</tr>
<tr>
<td></td>
<td>predictable</td>
</tr>
</tbody>
</table>

**Figure 46. BH field encodings**

---

**Programming Note**

The hint provided by the BH field is independent of the hint provided by the “at” bits (e.g., the BH field provides no indication of whether the branch is likely to be taken).

**Extended mnemonics for branches**

Many extended mnemonics are provided so that Branch Conditional instructions can be coded with portions of the BO and BI fields as part of the mnemonic rather than as part of a numeric operand. Some of these are shown as examples with the Branch instructions. See Appendix E for additional extended mnemonics.

---

**Programming Note**

The hints provided by the “at” bits and by the BH field do not affect the results of executing the instruction.

The “z” bits should be set to 0, because they may be assigned a meaning in some future version of the architecture.
Many implementations have dynamic mechanisms for predicting the target addresses of `bclr`[l] and `bcctr`[l] instructions. These mechanisms may cache return addresses (i.e., Link Register values set by `Branch` instructions for which `LK`=1 and for which the branch was taken, other than the special form shown in the first example below) and recently used branch target addresses. To obtain the best performance across the widest range of implementations, the programmer should obey the following rules.

- **Use `Branch` instructions for which `LK`=1 only as subroutine calls (including function calls, etc.), or in the special form shown in the first example below.**

- **Pair each subroutine call (i.e., each `Branch` instruction for which `LK`=1 and the branch is taken, other than the special form shown in the first example below) with a `bclr` instruction that returns from the subroutine and has BH=0b00.**

- **Do not use `bclrl` as a subroutine call. (Some implementations access the return address cache at most once per instruction; such implementations are likely to treat `bclrl` as a subroutine return, and not as a subroutine call.)**

- **For `bclr`[l] and `bcctr`[l], use the appropriate value in the BH field.**

The following are examples of programming conventions that obey these rules. In the examples, BH is assumed to contain 0b00 unless otherwise stated. In addition, the "at" bits are assumed to be coded appropriately.

Let A, B, and Glue be specific programs.

- **Obtaining the address of the next instruction:**
  Use the following form of `Branch and Link`.
  
  \[
  \text{bcl} \quad 20,31,\$+4
  \]

- **Loop counts:**
  Keep them in the Count Register, and use a `bc` instruction (LK=0) to decrement the count and to branch back to the beginning of the loop if the decremented count is nonzero.

- **Computed goto’s, case statements, etc.:**
  Use the Count Register to hold the address to branch to, and use a `bcctr` instruction (LK=0, and BH=0b11 if appropriate) to branch to the selected address.

- **Direct subroutine linkage:**
  Here A calls B and B returns to A. The two branches should be as follows.
  - A calls B: use a `bl` or `bcl` instruction (LK=1).
  - B returns to A: use a `bclr` instruction (LK=0) (the return address is in, or can be restored to, the Link Register).

- **Indirect subroutine linkage:**
  Here A calls Glue, Glue calls B, and B returns to A rather than to Glue. (Such a calling sequence is common in linkage code used when the subroutine that the programmer wants to call, here B, is in a different module from the caller; the Binder inserts "glue" code to mediate the branch.) The three branches should be as follows.
  - A calls Glue: use a `bl` or `bcl` instruction (LK=1).
  - Glue calls B: place the address of B into the Count Register, and use a `bcctr` instruction (LK=0).
  - B returns to A: use a `bclr` instruction (LK=0) (the return address is in, or can be restored to, the Link Register).

- **Function call:**
  Here A calls a function, the identity of which may vary from one instance of the call to another, instead of calling a specific program B. This case should be handled using the conventions of the preceding two bullets, depending on whether the call is direct or indirect, with the following differences.
  - If the call is direct, place the address of the function into the Count Register, and use a `bcctr` instruction (LK=1) instead of a `bl` or `bcl` instruction.
  - For the `bcctr`[l] instruction that branches to the function, use BH=0b11 if appropriate.
The bits corresponding to the current “a” and “t” bits, and to the current “z” bits except in the “branch always” BO encoding, had different meanings in versions of the architecture that precede Version 2.00.

- The bit corresponding to the “t” bit was called the “y” bit. The “y” bit indicated whether to use the architected default prediction (y=0) or to use the complement of the default prediction (y=1). The default prediction was defined as follows.
  - If the instruction is $bc{l}[[a]$ with a negative value in the displacement field, the branch is taken. (This is the only case in which the prediction corresponding to the “y” bit differs from the prediction corresponding to the “t” bit.)
  - In all other cases ($bc{l}[[a]$ with a nonnegative value in the displacement field, $bclr{l}$, or $bcctr{l}$), the branch is not taken.

- The BO encodings that test both the Count Register and the Condition Register had a “y” bit in place of the current “z” bit. The meaning of the “y” bit was as described in the preceding item.

- The “a” bit was a “z” bit.

Because these bits have always been defined either to be ignored or to be treated as hints, a given program will produce the same result on any implementation regardless of the values of the bits. Also, because even the “y” bit is ignored, in practice, by most processors that comply with versions of the architecture that precede Version 2.00, the performance of a given program on those processors will not be affected by the values of the bits.
### Branch I-form

- if AA then NIA $\leftarrow_{\text{lea}}$ EXTS(LI $||$ 0b00) $
- else NIA $\leftarrow_{\text{lea}}$ CIA + EXTS(LI $||$ 0b00) $
- if LK then LR $\leftarrow_{\text{lea}}$ CIA + 4 $

**target_addr** specifies the branch target address.

If AA=0 then the branch target address is the sum of LI $||$ 0b00 sign-extended and the address of this instruction, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If AA=1 then the branch target address is the value LI $||$ 0b00 sign-extended, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the Branch instruction is placed into the Link Register.

**Special Registers Altered:**

- LR (if LK=1)

### Branch Conditional B-form

#### Extended Mnemonics:

- Examples of extended mnemonics for **Branch Conditional**:

  - **Extended:**
    - blt target
    - bne cr2,target
    - bdnz target

  - **Equivalent to:**
    - bc 12,0,target
    - bc 4,10,target
    - bc 16,0,target
Branch Conditional to Link Register

**XL-form**

<table>
<thead>
<tr>
<th>bclr</th>
<th>BO,BI,BH (LK=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>bclrl</td>
<td>BO,BI,BH (LK=1)</td>
</tr>
</tbody>
</table>

if (64-bit mode)
then M ← 0
else M ← 32
if ¬BO2 then CTR ← CTR - 1
ctr_ok ← BO2 | ((CTR0:63 ≠ 0) ⊕ BO3)
cond_ok ← BO0 | (CRB1:32 = BO0)
if ctr_ok & cond_ok then NIA ← lea CTR0:61 || 0b00
if LK then LR ← lea CIA + 4

BI+32 specifies the Condition Register bit to be tested. The BO field is used to resolve the branch as described in Figure 44. The BH field is used as described in Figure 46. The branch target address is LR0:61 || 0b00, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the Branch instruction is placed into the Link Register.

**Special Registers Altered:**

CTR (if BO₂=0)
LR (if LK=1)

**Extended Mnemonics:**

Examples of extended mnemonics for Branch Conditional to Link Register:

<table>
<thead>
<tr>
<th>Extended</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>bclr</td>
<td>4,6</td>
</tr>
<tr>
<td>bclrl</td>
<td>4,6,0</td>
</tr>
<tr>
<td>btltlr</td>
<td>bclr 12,0,0</td>
</tr>
<tr>
<td>bnelr</td>
<td>bclr 4,10,0</td>
</tr>
<tr>
<td>bdnzlr</td>
<td>bclr 16,0,0</td>
</tr>
</tbody>
</table>

**Programming Note**

*bclr, bclrl, bcctr, and bcctrl* each serve as both a basic and an extended mnemonic. The Assembler will recognize a *bclr*, *bclrl*, *bcctr*, or *bcctrl* mnemonic with three operands as the basic form, and a *bclr*, *bclrl*, *bcctr*, or *bcctrl* mnemonic with two operands as the extended form. In the extended form the BH operand is omitted and assumed to be 0b00.

Branch Conditional to Count Register

**XL-form**

<table>
<thead>
<tr>
<th>bcctr</th>
<th>BO,BI,BH (LK=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>bcctrl</td>
<td>BO,BI,BH (LK=1)</td>
</tr>
</tbody>
</table>

cond_ok ← BO0 | (CRB1:32 = BO0)
if cond_ok then NIA ← lea CTR0:61 || 0b00
if LK then LR ← lea CIA + 4

BI+32 specifies the Condition Register bit to be tested. The BO field is used to resolve the branch as described in Figure 44. The BH field is used as described in Figure 46. The branch target address is CTR0:61 || 0b00, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the Branch instruction is placed into the Link Register.

If the “decrement and test CTR” option is specified (BO₂=0), the instruction form is invalid.

**Special Registers Altered:**

LR (if LK=1)

**Extended Mnemonics:**

Examples of extended mnemonics for Branch Conditional to Count Register:

<table>
<thead>
<tr>
<th>Extended</th>
<th>Equivalent to</th>
</tr>

</thead>
<tbody>
<tr>
<td>bctarl</td>
<td>BO, BI, BH (LK=1)</td>
</tr>
</tbody>
</table>

\[
\begin{array}{ccccccc}
19 & 8 & 11 & /// & BH & 560 & LK \\
0 & 0 & 1 & 0 & 0 & 0 & 0
\end{array}
\]

if (64-bit mode)
then \( M \leftarrow 0 \)
else \( M \leftarrow 32 \)
if \( \neg B0_2 \) then \( CTR \leftarrow CTR - 1 \)
\( \text{ctr_ok} \leftarrow B0_2 \mid (\text{CTR}_{-63} \neq 0) \oplus B0_4 \)
\( \text{cond_ok} \leftarrow B0_0 \mid (\text{CTR}_{-32} = B0_2) \)
if \( \text{ctr_ok} \& \text{cond_ok} \) then \( \text{NIA} \leftarrow \text{iea TAR}_{0,61} \mid 0b00 \)
if \( LK \) then \( \text{LR} \leftarrow \text{iea CIA + 4} \)

\( \text{BI+32} \) specifies the Condition Register bit to be tested. The \( \text{BO} \) field is used to resolve the branch as described in Figure 44. The \( \text{BH} \) field is used as described in Figure 46. The branch target address is \( \text{TAR}_{0,61} \mid 0b00 \), with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If \( \text{LK=1} \) then the effective address of the instruction following the \text{Branch} instruction is placed into the \text{Link Register}.

**Special Registers Altered:**

- \( \text{CTR} \) (if \( B0_2=0 \))
- \( \text{LR} \) (if \( LK=1 \))

**Programming Note**

In some systems, the system program will restrict usage of the \text{bctar/1} instruction to only selected programs. If an attempt is made to execute the instruction when it is not available, the system error handler will be invoked. See Book III-S for additional information.
2.6 Condition Register Instructions

2.6.1 Condition Register Logical Instructions

The Condition Register Logical instructions have preferred forms; see Section 1.8.1. In the preferred forms, the BT and BB fields satisfy the following rule.

- The bit specified by BT is in the same Condition Register field as the bit specified by BB.

### Condition Register AND

**XL-form**

\[
\text{crand} \quad \text{BT,BA,BB}
\]

<table>
<thead>
<tr>
<th>19</th>
<th>BT</th>
<th>BA</th>
<th>BB</th>
<th>257</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

\[\text{CR}_{BT+32} \leftarrow \text{CR}_{BA+32} \land \text{CR}_{BB+32}\]

The bit in the Condition Register specified by BA+32 is ANDed with the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\[\text{CR}_{BT+32}\]

### Condition Register NAND

**XL-form**

\[
\text{cmnand} \quad \text{BT,BA,BB}
\]

<table>
<thead>
<tr>
<th>19</th>
<th>BT</th>
<th>BA</th>
<th>BB</th>
<th>225</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

\[\text{CR}_{BT+32} \leftarrow \neg(\text{CR}_{BA+32} \land \text{CR}_{BB+32})\]

The bit in the Condition Register specified by BA+32 is ANDed with the bit in the Condition Register specified by BB+32, and the complemented result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\[\text{CR}_{BT+32}\]

### Condition Register OR

**XL-form**

\[
\text{cro} \quad \text{BT,BA,BB}
\]

<table>
<thead>
<tr>
<th>19</th>
<th>BT</th>
<th>BA</th>
<th>BB</th>
<th>449</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

\[\text{CR}_{BT+32} \leftarrow \text{CR}_{BA+32} \lor \text{CR}_{BB+32}\]

The bit in the Condition Register specified by BA+32 is ORed with the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\[\text{CR}_{BT+32}\]

### Condition Register XOR

**XL-form**

\[
\text{cxor} \quad \text{BT,BA,BB}
\]

<table>
<thead>
<tr>
<th>19</th>
<th>BT</th>
<th>BA</th>
<th>BB</th>
<th>193</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

\[\text{CR}_{BT+32} \leftarrow \text{CR}_{BA+32} \oplus \text{CR}_{BB+32}\]

The bit in the Condition Register specified by BA+32 is XORed with the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\[\text{CR}_{BT+32}\]

**Example of extended mnemonics for Condition Register OR:**

- **Extended:** crmove Bx,By
- **Equivalent to:** cro Bx,By,By

**Example of extended mnemonics for Condition Register XOR:**

- **Extended:** crcir Bx
- **Equivalent to:** cxor Bx,By,Bx

---

Extended mnemonics for Condition Register logical operations

A set of extended mnemonics is provided that allow additional Condition Register logical operations, beyond those provided by the basic Condition Register Logical instructions, to be coded easily. Some of these are shown as examples with the Condition Register Logical instructions. See Appendix E for additional extended mnemonics.
### Condition Register NOR

**XL-form**

<table>
<thead>
<tr>
<th>crnor</th>
<th>BT, BA, BB</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 19 33 /</td>
<td>5 11 16 21</td>
</tr>
</tbody>
</table>

\[
\text{\text{CR}}_{BT+32} \leftarrow \neg (\text{CR}_{BA+32} \mid \text{CR}_{BB+32})
\]

The bit in the Condition Register specified by BA+32 is ORed with the bit in the Condition Register specified by BB+32, and the complemented result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\[\text{CR}_{BT+32}\]

**Extended Mnemonics:**

Example of extended mnemonics for Condition Register NOR:

- **Extended:** crnot Bx, By
- **Equivalent to:** crnor Bx, By, By

### Condition Register Equivalent

**XL-form**

<table>
<thead>
<tr>
<th>creqv</th>
<th>BT, BA, BB</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 19 289 /</td>
<td>5 11 16 21</td>
</tr>
</tbody>
</table>

\[
\text{\text{CR}}_{BT+32} \leftarrow \neg \text{CR}_{BA+32} = \text{CR}_{BB+32}
\]

The bit in the Condition Register specified by BA+32 is XORed with the bit in the Condition Register specified by BB+32, and the complemented result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\[\text{CR}_{BT+32}\]

**Extended Mnemonics:**

Example of extended mnemonics for Condition Register Equivalent:

- **Extended:** crset Bx
- **Equivalent to:** creqv Bx, Bx, Bx

### Condition Register AND with Complement

**XL-form**

<table>
<thead>
<tr>
<th>crandc</th>
<th>BT, BA, BB</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 19 129 /</td>
<td>5 11 16 21</td>
</tr>
</tbody>
</table>

\[
\text{\text{CR}}_{BT+32} \leftarrow \text{CR}_{BA+32} \& \neg \text{CR}_{BB+32}
\]

The bit in the Condition Register specified by BA+32 is ANDed with the complement of the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\[\text{CR}_{BT+32}\]

### Condition Register OR with Complement

**XL-form**

<table>
<thead>
<tr>
<th>croc</th>
<th>BT, BA, BB</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 19 417 /</td>
<td>5 11 16 21</td>
</tr>
</tbody>
</table>

\[
\text{\text{CR}}_{BT+32} \leftarrow \text{CR}_{BA+32} \mid \neg \text{CR}_{BB+32}
\]

The bit in the Condition Register specified by BA+32 is ORed with the complement of the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\[\text{CR}_{BT+32}\]

### 2.6.2 Condition Register Field Instruction

**Move Condition Register Field**

**XL-form**

<table>
<thead>
<tr>
<th>mcrf</th>
<th>BF, BFA</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 19 31 /</td>
<td>5 11 14 16 21</td>
</tr>
</tbody>
</table>

\[
\text{\text{CR}}_{4\times\text{BF+32}:4\times\text{BFA+35}} \leftarrow \text{\text{CR}}_{4\times\text{BF+32}:4\times\text{BFA+35}}
\]

The contents of Condition Register field BFA are copied to Condition Register field BF.

**Special Registers Altered:**

\[\text{CR field BF}\]
2.7 System Call Instruction

This instruction provides the means by which a program can call upon the system to perform a service.

<table>
<thead>
<tr>
<th><strong>System Call</strong></th>
<th><strong>SC-form</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>sc LEV</td>
<td>17 6 /// /// 11 16 // LEV // 1 // 27 30 31</td>
</tr>
</tbody>
</table>

This instruction calls the system to perform a service. A complete description of this instruction can be found in Book III.

The use of the LEV field is described in Book III. The LEV values greater than 1 are reserved, and bits 0:5 of the LEV field (instruction bits 20:25) are treated as a reserved field.

When control is returned to the program that executed the System Call instruction, the contents of the registers will depend on the register conventions used by the program providing the system service.

This instruction is context synchronizing (see Book III).

**Special Registers Altered:**
Dependent on the system service

**Programming Note**

sc serves as both a basic and an extended mnemonic. The Assembler will recognize an sc mnemonic with one operand as the basic form, and an sc mnemonic with no operand as the extended form. In the extended form the LEV operand is omitted and assumed to be 0.

In application programs the value of the LEV operand for sc should be 0.
2.8 Branch History Rolling Buffer Instructions

The Branch History Rolling Buffer instructions enable problem state programs to access and clear the BHRB. The availability of these instructions is controlled by the system program. (See Chapter 9 of Book III-S.) When an attempt is made to execute these instructions when they are unavailable, the Facility Unavailable error handler is invoked.

**Clear BHRB**

* X-form

```
clrhhrb
```

for \( n = 0:1023 \)

\( \text{BHRB}(n) \leftarrow 0 \)

All BHRB entries are set to 0s.

**Special Registers Altered:**

None.

---

**Move From Branch History Rolling Buffer**

* XFX-form

```
mbhhrbe RT,BHRBE
```

\( n \leftarrow \text{bhrbe}_0,9 \)

If \( n < \text{number of BHRBEs implemented} \), then

\( \text{RT} \leftarrow \text{BHRBE}(n) \)

else

\( \text{RT} \leftarrow 0 \)

The BHRBE field denotes an entry in the BHRB. If the designated entry is within the range of BHRB entries implemented, the contents of the designated BHRB entry are placed into register RT; otherwise, 0s are placed into RT.

In order to ensure that the current BHRB contents are read by this instruction, an event-based branch or rfebbb (see Chapter 7 of Book II) or a non-recoverable interrupt or Return from Interrupt instruction (see Book III-S Chapter 6) must have occurred prior to this instruction and after all previous Branch and clrbhrb instructions have completed.

**Special Registers Altered:**

None

---

**Programming Note**

In order to read all the BHRB entries containing information about taken branches, software reads the entries starting from entry number 0 and continuing until an entry containing 0s is read or until all implemented BHRB entries have been read.

---

**Programming Note**

Since the number of BHRB entries may decrease or the BHRB may be cleared at any time, reading an entry for a second time may result in a zero value being returned even though the program has not executed clrbhrb.
Chapter 3. Fixed-Point Facility

3.1 Fixed-Point Facility Overview

This chapter describes the registers and instructions that make up the Fixed-Point Facility.

3.2 Fixed-Point Facility Registers

3.2.1 General Purpose Registers

All manipulation of information is done in registers internal to the Fixed-Point Facility. The principal storage internal to the Fixed-Point Facility is a set of 32 General Purpose Registers (GPRs). See Figure 47.

![Figure 47. General Purpose Registers](image)

Each GPR is a 64-bit register.

3.2.2 Fixed-Point Exception Register

The Fixed-Point Exception Register (XER) is a 64-bit register.

![Figure 48. Fixed-Point Exception Register](image)

The bit definitions for the Fixed-Point Exception Register are shown below. Here \( M=0 \) in 64-bit mode and \( M=32 \) in 32-bit mode.

<table>
<thead>
<tr>
<th>Bit(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0:31</td>
<td>Reserved</td>
</tr>
<tr>
<td>32</td>
<td><strong>Summary Overflow</strong> (SO)</td>
</tr>
<tr>
<td></td>
<td>The Summary Overflow bit is set to 1 whenever an instruction (except \textit{mtspr}) sets the Overflow bit. Once set, the SO bit remains set until it is cleared by an \textit{mtspr} instruction (specifying the XER) or an \textit{mcrxr} instruction. It is not altered by \textit{Compare} instructions, or by other instructions (except \textit{mtspr} to the XER, and \textit{mcrxr}) that cannot overflow. Executing an \textit{mtspr} instruction to the XER, supplying the values 0 for SO and 1 for OV, causes SO to be set to 0 and OV to be set to 1.</td>
</tr>
<tr>
<td>33</td>
<td><strong>Overflow</strong> (OV)</td>
</tr>
</tbody>
</table>
|        | The Overflow bit is set to indicate that an overflow has occurred during execution of an instruction. \( \text{XO-form Add, Subtract From, and Negate} \) instructions having OE=1 set it to 1 if the carry out of bit \( M \) is not equal to the carry out of bit \( M+1 \), and set it to 0 otherwise. \( \text{XO-form Multiply Low and Divide} \) instructions having OE=1 set it to 1 if the result cannot be represented in 64 bits (\textit{mulld, divd, divid, divdu, divdeu}) or in 32 bits (\textit{mulw, divw, divwe, divwu, divweu}), and set it to 0 otherwise. The OV bit is not altered by \textit{Compare} instructions.
instructions, or by other instructions (except \texttt{mtspr} to the XER, and \texttt{mcrxr}) that cannot overflow.

[Category: Legacy Integer Multiply-Accumulate]  
XO-form \textit{Legacy Integer Multiply-Accumulate} instructions set OV when OE=1 to reflect overflow of the 32-bit result. For signed-integer accumulation, overflow occurs when the add produces a carry out of bit 32 that is not equal to the carry out of bit 33. For unsigned-integer accumulation, overflow occurs when the add produces a carry out of bit 32.

\textbf{Carry (CA)}

The Carry bit is set as follows, during execution of certain instructions. \textit{Add Carrying}, \textit{Subtract From Carrying}, \textit{Add Extended}, and \textit{Subtract From Extended} types of instructions set it to 1 if there is a carry out of bit M, and set it to 0 otherwise. \textit{Shift Right Algebraic} instructions set it to 1 if any 1-bits have been shifted out of a negative operand, and set it to 0 otherwise. The CA bit is not altered by \textit{Compare} instructions, or by other instructions (except \textit{Shift Right Algebraic}, \texttt{mtspr} to the XER, and \texttt{mcrxr}) that cannot carry.

34:56 Reserved

57:63 This field specifies the number of bytes to be transferred by a \textit{Load String Indexed} or \textit{Store String Indexed} instruction.

[Category: Legacy Move Assist]

This field is used as a target by \texttt{dmlzb} to indicate the byte location of the leftmost zero byte found.

### 3.2.3 VR Save Register

The VR Save Register (VRSAVE) is a 32-bit register that can be used as a software use SPR; see Sections 3.2.4 and 5.3.3.

#### Architecture Note

In versions of the Architecture that precede Version 2.05, the VRSAVE Register was in the Vector category (see Section 5.3.3). It is now included in the Base category to simplify operating system support of and migration between heterogeneous systems containing processors with and without support for the Vector category.

### 3.2.4 Software Use SPRs [Category: Embedded]

Software Use SPRs are 64-bit registers that have no defined functionality. SPRG4-7 can be read by application programs. Additional Software Use SPRs are defined in Book III.

<table>
<thead>
<tr>
<th>SPRG4</th>
<th>SPRG5</th>
<th>SPRG6</th>
<th>SPRG7</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td>63</td>
</tr>
</tbody>
</table>

\textbf{Figure 49. Software-use SPRs}

\textbf{Programming Note}

USPRG0 was made a 32-bit register and renamed to VRSAVE; see Sections 3.2.3 and 5.3.3.

### 3.2.5 Device Control Registers [Category: Embedded.Device Control]

Device Control Registers (DCRs) are on-chip registers that exist architecturally outside the processor and thus are not actually part of the processor architecture. This specification simply defines the existence of a Device Control Register ‘address space’ and the instructions to access them and does not define the Device Control Registers themselves.

Device Control Registers may control the use of on-chip peripherals, such as memory controllers (the definition of specific Device Control Registers is implementation-dependent).

The contents of user-mode-accessible Device Control Registers can be read using \texttt{mfdcrux} and written using \texttt{mtdcrux}.
3.3 Fixed-Point Facility Instructions

3.3.1 Fixed-Point Storage Access Instructions

The Storage Access instructions compute the effective address (EA) of the storage to be accessed as described in Section 1.10.3 on page 26.

Programming Note

The ia extended mnemonic permits computing an effective address as a Load or Store instruction would, but loads the address itself into a GPR rather than loading the value that is in storage at that address.

3.3.1.1 Storage Access Exceptions

Storage accesses will cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (Store only), or if the program attempts to access storage that is unavailable.

3.3.2 Fixed-Point Load Instructions

The byte, halfword, word, or doubleword in storage addressed by EA is loaded into register RT.

Many of the Load instructions have an “update” form, in which register RA is updated with the effective address. For these forms, if RA≠0 and RA≠RT, the effective address is placed into register RA and the storage element (byte, halfword, word, or doubleword) addressed by EA is loaded into RT.

Programming Note

In some implementations, the Load Algebraic and Load with Update instructions may have greater latency than other types of Load instructions. Moreover, Load with Update instructions may take longer to execute in some implementations than the corresponding pair of a non-update Load instruction and an Add instruction.
### Load Byte and Zero

**D-form**

\[
\text{lbz} \quad RT, D(RA)
\]

<table>
<thead>
<tr>
<th>0</th>
<th>34</th>
<th>RT</th>
<th>11</th>
<th>RA</th>
<th>16</th>
<th>D</th>
<th>31</th>
</tr>
</thead>
</table>

if RA = 0 then \( b \leftarrow 0 \)
else \( b \leftarrow (RA) \)

\( EA \leftarrow b + \text{EXTS}(D) \)
\( RT \leftarrow 560 \| \text{MEM}(EA, 1) \)

Let the effective address (EA) be the sum \((RA|0)+ D\). The byte in storage addressed by EA is loaded into \( RT_{56:63} \). \( RT_{0:55} \) are set to 0.

**Special Registers Altered:**

None

---

### Load Byte and Zero Indexed

**X-form**

\[
\text{lbzx} \quad RT, RA, RB
\]

| 0 | 31 | RT | 11 | RA | 16 | RB | 87 | /
|---|----|----|----|----|----|----|----|-----|

if RA = 0 then \( b \leftarrow 0 \)
else \( b \leftarrow (RA) \)

\( EA \leftarrow b + (RB) \)
\( RT \leftarrow 560 \| \text{MEM}(EA, 1) \)

Let the effective address (EA) be the sum \((RA|0)+ (RB)\). The byte in storage addressed by EA is loaded into \( RT_{56:63} \). \( RT_{0:55} \) are set to 0.

**Special Registers Altered:**

None

---

### Load Byte and Zero with Update

**D-form**

\[
\text{lbzu} \quad RT, D(RA)
\]

<table>
<thead>
<tr>
<th>0</th>
<th>35</th>
<th>RT</th>
<th>11</th>
<th>RA</th>
<th>16</th>
<th>D</th>
<th>31</th>
</tr>
</thead>
</table>

\( EA \leftarrow (RA) + \text{EXTS}(D) \)
\( RT \leftarrow 560 \| \text{MEM}(EA, 1) \)
\( RA \leftarrow EA \)

Let the effective address (EA) be the sum \((RA)+ D\). The byte in storage addressed by EA is loaded into \( RT_{56:63} \). \( RT_{0:55} \) are set to 0.

EA is placed into register RA.

If RA=0 or RA=RT, the instruction form is invalid.

**Special Registers Altered:**

None

---

### Load Byte and Zero with Update Indexed

**X-form**

\[
\text{lbzux} \quad RT, RA, RB
\]

| 0 | 31 | RT | 11 | RA | 16 | RB | 119 | /
|---|----|----|----|----|----|----|-----|-----|

\( EA \leftarrow (RA) + (RB) \)
\( RT \leftarrow 560 \| \text{MEM}(EA, 1) \)
\( RA \leftarrow EA \)

Let the effective address (EA) be the sum \((RA)+(RB)\). The byte in storage addressed by EA is loaded into \( RT_{56:63} \). \( RT_{0:55} \) are set to 0.

EA is placed into register RA.

If RA=0 or RA=RT, the instruction form is invalid.

**Special Registers Altered:**

None
### Load Halfword and Zero

#### Implementation Details

EA ← (RA) + (RB)
RT ← MEM(EA, 8)
RA ← EA

Let the effective address (EA) be the sum (RA|0) + (RB). The doubleword in storage addressed by EA is loaded into RT.

**Special Registers Altered:** None

**Notes:**
If RA=0 or RA=RT, the instruction form is invalid.
3.3.3 Fixed-Point Store Instructions

The contents of register RS are stored into the byte, halfword, word, or doubleword in storage addressed by EA.

Many of the Store instructions have an “update” form, in which register RA is updated with the effective address. For these forms, the following rules apply.

- If RA ≠ 0, the effective address is placed into register RA.
- If RS=RA, the contents of register RS are copied to the target storage element and then EA is placed into RA (RS).

### Store Byte

<table>
<thead>
<tr>
<th>D-form</th>
<th>Store Byte Indexed</th>
<th>X-form</th>
</tr>

3.3.6 Fixed-Point Load and Store Multiple Instructions

The *Load/Store Multiple* instructions have preferred forms; see Section 1.8.1, “Preferred Instruction Forms” on page 22. In the preferred forms, storage alignment satisfies the following rule.

The combination of the EA and RT (RS) is such that the low-order byte of GPR 31 is loaded (stored) from (into) the last byte of an aligned quadword in storage.

For the Server environment, the *Load/Store Multiple* instructions are not supported in Little-Endian mode. If they are executed in Little-Endian mode, the system alignment error handler is invoked.

    r ← r + 1
    EA ← EA + 4

Let n = (32–RS). Let the effective address (EA) be the sum (RA|0)+ D.

n consecutive words starting at EA are stored from the low-order 32 bits of GPRs RS through 31.

**Special Registers Altered:**

None
3.3.7 Fixed-Point Move Assist Instructions [Category: Move Assist]

The *Move Assist* instructions allow movement of data from storage to registers or from registers to storage without concern for alignment. These instructions can be used for a short move between arbitrary storage locations or to initiate a long move between unaligned storage fields.

The *Load/Store String* instructions have preferred forms; see Section 1.8.1, “Preferred Instruction Forms” on page 22. In the preferred forms, register usage satisfies the following rules.

- RS = 4 or 5
- RT = 4 or 5
- Last register loaded/stored ≤ 12

For some implementations, using GPR 4 for RS and RT may result in slightly faster execution than using GPR 5.

For the Server environment, the *Move Assist* instructions are not supported in Little-Endian mode. If they are executed in Little-Endian mode, the system alignment error handler may be invoked or the instructions may be treated as no-ops if the number of bytes specified by the instruction is 0.
Load String Word Immediate

3.3.8 Other Fixed-Point Instructions

The remainder of the fixed-point instructions use the contents of the General Purpose Registers (GPRs) as source operands, and place results into GPRs, into the Fixed-Point Exception Register (XER), and into Condition Register fields. In addition, the Trap instructions test the contents of a GPR or XER bit, invoking the system trap handler if the result of the specified test is true.

These instructions treat the source operands as signed integers unless the instruction is explicitly identified as performing an unsigned operation.

The X-form and XO-form instructions with \( R_c = 1 \), and the D-form instructions \textit{addic}. \textit{andi}. and \textit{andis}. set the first three bits of CR Field 0 to characterize the result placed into the target register. In 64-bit mode, these bits are set by signed comparison of the result to zero. In 32-bit mode, these bits are set by signed comparison of the low-order 32 bits of the result to zero.

Unless otherwise noted and when appropriate, when CR Field 0 and the XER are set they reflect the value placed into the target register.

</tbody>
</table>
3.3.9 Fixed-Point Arithmetic Instructions

The XO-form Arithmetic instructions with Rc=1, and the D-form Arithmetic instruction addic., set the first three bits of CR Field 0 as described in Section 3.3.8, “Other Fixed-Point Instructions”. addic, addic., subfic, addc, subfc, adde, subfe, addme, subfme, addze, and subfze always set CA, to reflect the carry out of bit 0 in 64-bit mode and out of bit 32 in 32-bit mode. The XO-form Arithmetic instructions set SO and OV when OE=1 to reflect overflow of the result. Except for the Multiply Low and Divide instructions, the setting of these bits is mode-dependent, and reflects overflow of the 64-bit result in 64-bit mode and overflow of the low-order 32-bit result in 32-bit mode. For XO-form Multiply Low and Divide instructions, the setting of these bits is mode-independent, and reflects overflow of the 64-bit result for mulld, divd, divide, divdu and divideu, and overflow of the low-order 32-bit result for mullw, divw, divwe, divwu, and divweu.

Extended mnemonics for addition and subtraction

Several extended mnemonics are provided that use the Add Immediate and Add Immediate Shifted instructions to load an immediate value or an address into a target register. Some of these are shown as examples with the two instructions.

The Power ISA supplies Subtract From instructions, which subtract the second operand from the third. A set of extended mnemonics is provided that use the more “normal” order, in which the third operand is subtracted from the second, with the third operand being either an immediate field or a register. Some of these are shown as examples with the appropriate Add and Subtract From instructions.

See Appendix E for additional extended mnemonics.

Add Immediate
addi RT,RA,SI

D-form

| 14 | 5 | 11 | 16 | 31 |
---|---|---|---|---|
0  | 6 | RA | SI |

if RA = 0 then RT ← EXTS(SI)
else RT ← (RA) + EXTS(SI)

The sum (RA0) + SI is placed into register RT.

Special Registers Altered:
None

Extended Mnemonics:
Examples of extended mnemonics for Add Immediate:

<table>
<thead>
<tr>
<th>Extended</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>li Rx,value</td>
<td>addi Rx,0,value</td>
</tr>
<tr>
<td>la Rx,disp(Ry)</td>
<td>addi Rx,Ry,disp</td>
</tr>
<tr>
<td>subi Rx,Ry,value</td>
<td>addi Rx,Ry,-value</td>
</tr>
</tbody>
</table>

Programming Note
addi, addis, add, and subf are the preferred instructions for addition and subtraction, because they set few status bits.

Notice that addi and addis use the value 0, not the contents of GPR 0, if RA=0.

Add Immediate Shifted
addis RT,RA,SI

D-form

| 15 | 6 | 11 | 16 | 31 |
---|---|---|---|---|
0  | 5 | RA | SI |

if RA = 0 then RT ← EXTS(SI || 160)
else RT ← (RA) + EXTS(SI || 160)

The sum (RA0) + (SI || 0x0000) is placed into register RT.

Special Registers Altered:
None

Extended Mnemonics:
Examples of extended mnemonics for Add Immediate Shifted:

<table>
<thead>
<tr>
<th>Extended</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>lis Rx,value</td>
<td>addis Rx,0,value</td>
</tr>
<tr>
<td>subis Rx,Ry,value</td>
<td>addis Rx,Ry,-value</td>
</tr>
</tbody>
</table>
### Add

<table>
<thead>
<tr>
<th>Operation</th>
<th>Mnemonics</th>
<th>Form</th>
<th>Special Registers Altered</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add</td>
<td>add</td>
<td>RT,RA,RB</td>
<td>(OE=0 Rc=0)</td>
</tr>
<tr>
<td></td>
<td>add.</td>
<td>RT,RA,RB</td>
<td>(OE=0 Rc=1)</td>
</tr>
<tr>
<td></td>
<td>addo</td>
<td>RT,RA,RB</td>
<td>(OE=1 Rc=0)</td>
</tr>
<tr>
<td></td>
<td>addo.</td>
<td>RT,RA,RB</td>
<td>(OE=1 Rc=1)</td>
</tr>
</tbody>
</table>

**Example:**

\[
RT \leftarrow (RA) + (RB)
\]

The sum \((RA) + (RB)\) is placed into register RT.

**Special Registers Altered:**
- CR0 (if \(Rc=1\))
- SO OV (if \(OE=1\))

### Subtract From

<table>
<thead>
<tr>
<th>Operation</th>
<th>Mnemonics</th>
<th>Form</th>
<th>Special Registers Altered</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subtract From</td>
<td>subf</td>
<td>RT,RA,RB</td>
<td>(OE=0 Rc=0)</td>
</tr>
<tr>
<td></td>
<td>subf.</td>
<td>RT,RA,RB</td>
<td>(OE=0 Rc=1)</td>
</tr>
<tr>
<td></td>
<td>subfo</td>
<td>RT,RA,RB</td>
<td>(OE=1 Rc=0)</td>
</tr>
<tr>
<td></td>
<td>subfo.</td>
<td>RT,RA,RB</td>
<td>(OE=1 Rc=1)</td>
</tr>
</tbody>
</table>

**Example:**

\[
RT \leftarrow \neg (RA) + (RB) + 1
\]

The sum \(\neg (RA) + (RB) + 1\) is placed into register RT.

**Special Registers Altered:**
- CR0 (if \(Rc=1\))
- SO OV (if \(OE=1\))

### Add Immediate Carrying

<table>
<thead>
<tr>
<th>Operation</th>
<th>Mnemonics</th>
<th>Form</th>
<th>Special Registers Altered</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Immediate Carrying</td>
<td>addic</td>
<td>RT,RA,SI</td>
<td></td>
</tr>
</tbody>
</table>

**Example:**

\[
RT \leftarrow (RA) + \text{EXTS}(SI)
\]

The sum \((RA) + \text{SI}\) is placed into register RT.

**Special Registers Altered:**
- CA

### Add Immediate Carrying and Record

<table>
<thead>
<tr>
<th>Operation</th>
<th>Mnemonics</th>
<th>Form</th>
<th>Special Registers Altered</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Immediate Carrying and Record</td>
<td>addic.</td>
<td>RT,RA,SI</td>
<td></td>
</tr>
</tbody>
</table>

**Example:**

\[
RT \leftarrow (RA) + \text{EXTS}(SI)
\]

The sum \((RA) + \text{SI}\) is placed into register RT.

**Special Registers Altered:**
- CR0 CA

### Extended Mnemonics:

- **Example of extended mnemonics for Add Immediate Carrying:**
  - **Extended:**
    - subic Rx,Ry,value
  - **Equivalent to:**
    - addic Rx,Ry,−value

- **Example of extended mnemonics for Add Immediate Carrying and Record:**
  - **Extended:**
    - subic. Rx,Ry,value
  - **Equivalent to:**
    - addic. Rx,Ry,−value
**Subtract From Immediate Carrying**

*D-form*

\[
\text{subfic} \quad \text{RT}, \text{RA}, \text{SI}
\]

\[
\begin{array}{c|c|c|c|c|c}
8 & 6 & 11 & 16 & 31 \\
0 & 6 & 11 & 16 & 31 \\
\end{array}
\]

\[\text{RT} \leftarrow \neg(\text{RA}) + \text{EXTS(SI)} + 1\]

The sum \(\neg(\text{RA}) + \text{SI} + 1\) is placed into register RT.

**Special Registers Altered:**
- CA

---

**Add Carrying**

*XO-form*

\[
\text{addc} \quad \text{RT}, \text{RA}, \text{RB} \\
\text{addc}. \quad \text{RT}, \text{RA}, \text{RB} \\
\text{addco} \quad \text{RT}, \text{RA}, \text{RB} \\
\text{addco}. \quad \text{RT}, \text{RA}, \text{RB}
\]

\[
\begin{array}{c|c|c|c|c|c|c|c|c|c|c|c|c}
31 & 8 & 6 & 11 & 16 & 21 & 22 & 31 \\
0 & 6 & 11 & 16 & 21 & 22 & 31 \\
\end{array}
\]

\[\text{RT} \leftarrow (\text{RA}) + (\text{RB})\]

The sum \((\text{RA}) + (\text{RB})\) is placed into register RT.

**Special Registers Altered:**
- CA
- CR0 (if Rc=1)
- SO OV (if OE=1)

---

**Subtract From Carrying**

*XO-form*

\[
\text{subfc} \quad \text{RT}, \text{RA}, \text{RB} \\
\text{subfc}. \quad \text{RT}, \text{RA}, \text{RB} \\
\text{subfco} \quad \text{RT}, \text{RA}, \text{RB} \\
\text{subfco}. \quad \text{RT}, \text{RA}, \text{RB}
\]

\[
\begin{array}{c|c|c|c|c|c|c|c|c|c|c|c|c}
31 & 8 & 6 & 11 & 16 & 21 & 22 & 31 \\
0 & 6 & 11 & 16 & 21 & 22 & 31 \\
\end{array}
\]

\[\text{RT} \leftarrow \neg(\text{RA}) + (\text{RB}) + 1\]

The sum \(\neg(\text{RA}) + (\text{RB}) + 1\) is placed into register RT.

**Special Registers Altered:**
- CA
- CR0 (if Rc=1)
- SO OV (if OE=1)

**Extended Mnemonics:**

Example of extended mnemonics for **Subtract From Carrying**:

\[
\text{Extended:} \quad \text{Equivalent to:}
\]

\[
\begin{array}{c|c|c|c|c|c|c|c|c|c|c|c|c}
\text{subc} \quad \text{Rx}, \text{Ry}, \text{Rz} & \text{subfc} \quad \text{Rx}, \text{Rz}, \text{Ry}
\end{array}
\]
### Add Extended XO-form

<table>
<thead>
<tr>
<th>Instruction</th>
<th>RT,RA, RB</th>
<th>OE=0 Rc=0</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>addde</code></td>
<td>RT,RA, RB</td>
<td>OE=0 Rc=0</td>
</tr>
<tr>
<td><code>addde</code></td>
<td>RT,RA, RB</td>
<td>OE=1 Rc=0</td>
</tr>
<tr>
<td><code>adddeo</code></td>
<td>RT,RA, RB</td>
<td>OE=1 Rc=1</td>
</tr>
<tr>
<td><code>adddeo</code></td>
<td>RT,RA, RB</td>
<td>OE=1 Rc=1</td>
</tr>
</tbody>
</table>

The sum (RA) + (RB) + CA is placed into register RT.

### Subtract From Extended XO-form

<table>
<thead>
<tr>
<th>Instruction</th>
<th>RT,RA, RB</th>
<th>OE=0 Rc=0</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>subfe</code></td>
<td>RT,RA, RB</td>
<td>OE=0 Rc=0</td>
</tr>
<tr>
<td><code>subfe</code></td>
<td>RT,RA, RB</td>
<td>OE=1 Rc=0</td>
</tr>
<tr>
<td><code>subfeo</code></td>
<td>RT,RA, RB</td>
<td>OE=1 Rc=1</td>
</tr>
<tr>
<td><code>subfeo</code></td>
<td>RT,RA, RB</td>
<td>OE=1 Rc=1</td>
</tr>
</tbody>
</table>

The sum ¬(RA) + (RB) + CA is placed into register RT.

### Add to Minus One Extended XO-form

<table>
<thead>
<tr>
<th>Instruction</th>
<th>RT,RA</th>
<th>OE=0 Rc=0</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>addme</code></td>
<td>RT,RA</td>
<td>OE=0 Rc=0</td>

<tr>
<td><code>addmeo</code></td>
<td>RT,RA</td>
<td>OE=1 Rc=1</td>
</tr>
<tr>
<td><code>addmeo</code></td>
<td>RT,RA</td>
<td>OE=1 Rc=1</td>
</tr>
</tbody>
</table>

The sum (RA) + CA - 1 is placed into register RT.

### Subtract From Minus One Extended XO-form

<table>
<thead>
<tr>
<th>Instruction</th>
<th>RT,RA</th>
<th>OE=0 Rc=0</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>subfme</code></td>
<td>RT,RA</td>
<td>OE=0 Rc=0</td>
</tr>
<tr>
<td><code>subfme</code></td>
<td>RT,RA</td>
<td>OE=1 Rc=0</td>
</tr>
<tr>
<td><code>subfmeo</code></td>
<td>RT,RA</td>
<td>OE=1 Rc=1</td>
</tr>
<tr>
<td><code>subfmeo</code></td>
<td>RT,RA</td>
<td>OE=1 Rc=1</td>
</tr>
</tbody>
</table>

The sum ¬(RA) + CA - 1 is placed into register RT.
### Add to Zero Extended  
**XO-form**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>RT, RA</th>
<th>OE</th>
<th>Rc</th>
</tr>
</thead>
<tbody>
<tr>
<td>addze</td>
<td>RT, RA</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>addze.</td>
<td>RT, RA</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>addzeo</td>
<td>RT, RA</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>addzeo.</td>
<td>RT, RA</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

The sum \((RA) + CA\) is placed into register RT.

**Special Registers Altered:**
- CA
- CR0 (if Rc=1)
- SO OV (if OE=1)

### Subtract From Zero Extended  
**XO-form**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>RT, RA</th>
<th>OE</th>
<th>Rc</th>
</tr>
</thead>
<tbody>
<tr>
<td>subfze</td>
<td>RT, RA</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>subfze.</td>
<td>RT, RA</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>subfzeo</td>
<td>RT, RA</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>subfzeo.</td>
<td>RT, RA</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

The sum \(\neg(RA) + CA\) is placed into register RT.

**Special Registers Altered:**
- CA
- CR0 (if Rc=1)
- SO OV (if OE=1)

---

### Negate  
**XO-form**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>RT, RA</th>
<th>OE</th>
<th>Rc</th>
</tr>
</thead>
<tbody>
<tr>
<td>neg</td>
<td>RT, RA</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>neg.</td>
<td>RT, RA</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>nego</td>
<td>RT, RA</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>nego.</td>
<td>RT, RA</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

The sum \(\neg(RA) + 1\) is placed into register RT.

If the processor is in 64-bit mode and register RA contains the most negative 64-bit number \((0x8000_0000_0000_0000)\), the result is the most negative number and, if OE=1, OV is set to 1. Similarly, if the processor is in 32-bit mode and \((RA)_{32:63}\) contain the most negative 32-bit number \((0x8000_0000)\), the low-order 32 bits of the result contain the most negative 32-bit number and, if OE=1, OV is set to 1.

**Special Registers Altered:**
- CR0 (if Rc=1)
- SO OV (if OE=1)
### Multiply Low Immediate  

**D-form**

\[
mulli \quad RT, RA, SI
\]

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RT</td>
<td>RA</td>
<td>SI</td>
<td></td>
</tr>
</tbody>
</table>

\[\text{prod}_{0:127} \leftarrow (\text{RA}) \times \text{EXTS}[\text{SI}]\]

\[\text{RT} \leftarrow \text{prod}_{64:127}\]

The 64-bit first operand is (RA). The 64-bit second operand is the sign-extended value of the SI field. The low-order 64 bits of the 128-bit product of the operands are placed into register RT.

Both operands and the product are interpreted as signed integers.

**Special Registers Altered:**

None

### Multiply Low Word  

**XO-form**

\[
mullw \quad \text{RT}, RA, RB (\text{OE}=0 \text{ Rc}=0)
mullw. \quad \text{RT}, RA, RB (\text{OE}=0 \text{ Rc}=1)
mullwo \quad \text{RT}, RA, RB (\text{OE}=1 \text{ Rc}=0)
mullwo. \quad \text{RT}, RA, RB (\text{OE}=1 \text{ Rc}=1)
\]

<table>
<thead>
<tr>
<th>31</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>22</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>RT</td>
<td>RA</td>
<td>RB</td>
<td>OE</td>
<td>235</td>
<td>Rc</td>
<td></td>
</tr>
</tbody>
</table>

\[\text{RT}_{32:63} \leftarrow (\text{RA}_{32:63} \times \text{RB}_{32:63})\]

The 32-bit operands are the low-order 32 bits of RA and of RB. The 64-bit product of the operands is placed into register RT.

If OE=1 then OV is set to 1 if the product cannot be represented in 32 bits.

Both operands and the product are interpreted as signed integers.

**Special Registers Altered:**

\[\text{CR0} \quad (\text{if Rc}=1)\]
\[\text{SO OV} \quad (\text{if OE}=1)\]

#### Programming Note

For \textit{mulli} and \textit{mullw}, the low-order 32 bits of the product are the correct 32-bit product for 32-bit mode.

For \textit{mulli} and \textit{mulld}, the low-order 64 bits of the product are independent of whether the operands are regarded as signed or unsigned 64-bit integers.

For \textit{mulli} and \textit{mullw}, the low-order 32 bits of the product are independent of whether the operands are regarded as signed or unsigned 32-bit integers.

### Multiply High Word  

**XO-form**

\[
mulhw \quad \text{RT}, RA, RB (\text{Rc}=0)
mulhw. \quad \text{RT}, RA, RB (\text{Rc}=1)
\]

<table>
<thead>
<tr>
<th>31</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>22</th>
<th>75</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>RT</td>
<td>RA</td>
<td>RB</td>
<td>OE</td>
<td>235</td>
<td>/</td>
<td>22</td>
<td>Rc</td>
</tr>
</tbody>
</table>

\[\text{prod}_{0:63} \leftarrow (\text{RA}_{32:63} \times \text{RB}_{32:63})\]

\[\text{RT}_{32:63} \leftarrow \text{prod}_{0:63}\]

\[\text{RT}_{0:31} \leftarrow \text{undefined}\]

The 32-bit operands are the low-order 32 bits of RA and of RB. The high-order 32 bits of the 64-bit product of the operands are placed into RT\text{.}_{32:63}. The contents of RT\text{.}_{0:31} are undefined.

Both operands and the product are interpreted as signed integers.

**Special Registers Altered:**

\[\text{CR0} \quad (\text{bits 0:2 undefined in 64-bit mode}) \quad (\text{if Rc}=1)\]

### Multiply High Word Unsigned  

**XO-form**

\[
mulhwu \quad \text{RT}, RA, RB (\text{Rc}=0)
mulhwu. \quad \text{RT}, RA, RB (\text{Rc}=1)
\]

<table>
<thead>
<tr>
<th>31</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>22</th>
<th>11</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>RT</td>
<td>RA</td>
<td>RB</td>
<td>OE</td>
<td>235</td>
<td>/</td>
<td>22</td>
<td>Rc</td>
</tr>
</tbody>
</table>

\[\text{prod}_{0:63} \leftarrow (\text{RA}_{32:63} \times \text{RB}_{32:63})\]

\[\text{RT}_{32:63} \leftarrow \text{prod}_{0:63}\]

\[\text{RT}_{0:31} \leftarrow \text{undefined}\]

The 32-bit operands are the low-order 32 bits of RA and of RB. The high-order 32 bits of the 64-bit product of the operands are placed into RT\text{.}_{32:63}. The contents of RT\text{.}_{0:31} are undefined.

Both operands and the product are interpreted as unsigned integers, except that if Rc=1 the first three bits of CR Field 0 are set by signed comparison of the result to zero.

**Special Registers Altered:**

\[\text{CR0} \quad (\text{bits 0:2 undefined in 64-bit mode}) \quad (\text{if Rc}=1)\]
Divide Word

**XO-form**

- `divw` RT,RA,RB (OE=0 Rc=0)
- `divw` RT,RA,RB (OE=0 Rc=1)
- `divwo` RT,RA,RB (OE=1 Rc=0)
- `divwo` RT,RA,RB (OE=1 Rc=1)

<table>
<thead>
<tr>
<th>31</th>
<th>8</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>22</th>
<th>31</th>
</tr>
</thead>
</table>
| dividend_{0:31} &lt; (RA)_{32:63}  
divisor_{0:31} &lt; (RB)_{32:63}  
RT_{32:63} &lt; dividend + divisor  
RT_{0:31} &lt; undefined |

The 32-bit dividend is (RA)_{32:63}. The 32-bit divisor is (RB)_{32:63}. The 32-bit quotient is placed into RT_{32:63}. The contents of RT_{0:31} are undefined. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as signed integers. The quotient is the unique signed integer that satisfies

\[
dividend = (\text{quotient} \times \text{divisor}) + r
\]

where \(0 \leq r < |\text{divisor}|\) if the dividend is nonnegative, and \(-|\text{divisor}| < r \leq 0\) if the dividend is negative.

If an attempt is made to perform any of the divisions

\[
0x8000_0000 \div -1  
<\text{anything}> \div 0
\]

then the contents of register RT are undefined as are (if Rc=1) the contents of the LT, GT, and EO bits of CR Field 0. In these cases, if OE=1 then OV is set to 1.

**Special Registers Altered:**

- CR0 (bits 0:2 undefined in 64-bit mode) (if Rc=1)
- SO OV (if OE=1)

**Programming Note**

The 32-bit signed remainder of dividing (RA)_{32:63} by (RB)_{32:63} can be computed as follows, except in the case that (RA)_{32:63} = -2^{31} and (RB)_{32:63} = -1.

\[
\text{divw} \quad \text{RT},\text{RA},\text{RB} \quad \# \ RT = \text{quotient}  
\text{mullw} \quad \text{RT},\text{RT},\text{RB} \quad \# \ RT = \text{quotient} \times \text{divisor}  
\text{subf} \quad \text{RT},\text{RT},\text{RA} \quad \# \ RT = \text{remainder}
\]

Divide Word Unsigned

**XO-form**

- `divwu` RT,RA,RB (OE=0 Rc=0)
- `divwu` RT,RA,RB (OE=0 Rc=1)

[Category: Server]
[Category: Embedded.Phased-In]

**Dividend**

\[
\text{dividend}_{0:63} \leftarrow (RA)_{32:63} \ || \ 320
\]

**Divisor**

\[
\text{divisor}_{0:31} \leftarrow (RB)_{32:63}
\]

**Quotient**

\[
RT_{32:63} \leftarrow \text{dividend} + \text{divisor}
\]

\[
RT_{0:31} \leftarrow \text{undefined}
\]

The 64-bit dividend is \((RA)_{32:63} \ || \ 320\). The 32-bit divisor is \((RB)_{32:63}\). If the quotient can be represented in 32 bits, it is placed into \(RT_{32:63}\). The contents of \(RT_{0:31}\) are undefined. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as signed integers. The quotient is the unique signed integer that satisfies

\[
\text{dividend} = (\text{quotient} \times \text{divisor}) + r
\]

where \(0 \leq r < |\text{divisor}|\) if the dividend is nonnegative, and \(-|\text{divisor}| < r \leq 0\) if the dividend is negative.

If the quotient cannot be represented in 32 bits, or if an attempt is made to perform the division

\[
\langle\text{anything} \rangle \div 0
\]

then the contents of register RT are undefined as are (if Rc=1) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if OE=1 then OV is set to 1.

**Special Registers Altered:**

- CR0 (bits 0:2 undefined in 64-bit mode) (if Rc=1)
- SO OV (if OE=1)

---

**Divide Word Extended Unsigned**

<table>
<thead>
<tr>

[Category: Server]
[Category: Embedded.Phased-In]

**Dividend**

\[
\text{dividend}_{0:63} \leftarrow (RA)_{32:63} \ || \ 320
\]

**Divisor**

\[
\text{divisor}_{0:31} \leftarrow (RB)_{32:63}
\]

**Quotient**

\[
RT_{32:63} \leftarrow \text{dividend} + \text{divisor}
\]

\[
RT_{0:31} \leftarrow \text{undefined}
\]

The 64-bit dividend is \((RA)_{32:63} \ || \ 320\). The 32-bit divisor is \((RB)_{32:63}\). If the quotient can be represented in 32 bits, it is placed into \(RT_{32:63}\). The contents of \(RT_{0:31}\) are undefined. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as unsigned integers, except that if Rc=1 the first three bits of CR Field 0 are set by signed comparison of the result to zero. The quotient is the unique unsigned integer that satisfies

\[
\text{dividend} = (\text{quotient} \times \text{divisor}) + r
\]

where \(0 \leq r < \text{divisor}\).

If (RA) \(\geq\) (RB), or if an attempt is made to perform the division

\[
\langle\text{anything} \rangle \div 0
\]

then the contents of register RT are undefined as are (if Rc=1) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if OE=1 then OV is set to 1.

**Special Registers Altered:**

- CR0 (bits 0:2 undefined in 64-bit mode) (if Rc=1)
- SO OV (if OE=1)
Programming Note

Unsigned long division of a 64-bit dividend contained in two 32-bit registers by a 32-bit divisor can be computed as follows. The algorithm is shown first, followed by Assembler code that implements the algorithm. The dividend is \( \text{Dh} \| \text{Dl} \), the divisor is \( \text{Dv} \), and the quotient and remainder are \( Q \) and \( R \) respectively, where these variables and all intermediate variables represent unsigned 32-bit integers. It is assumed that \( \text{Dv} > \text{Dh} \), and that assigning a value to an intermediate variable assigns the low-order 32 bits of the value and ignores any higher-order bits of the value. (In both the algorithm and the Assembler code, “r1” and “r2” refer to “remainder 1” and “remainder 2”, rather than to GPRs 1 and 2.)

Algorithm:

3. \( q_1 \leftarrow \text{divweu} \text{Dh, Dv} \) 
4. \( r_1 \leftarrow -(q_1 \times \text{Dv}) \) \# remainder of step 1
   divide operation (see Note 1)
5. \( q_2 \leftarrow \text{divwu} \text{Dl, Dv} \)
6. \( r_2 \leftarrow \text{Dl} - (q_2 \times \text{Dv}) \) \# remainder of step 2
   divide operation
7. \( Q \leftarrow q_1 + q_2 \)
8. \( R \leftarrow r_1 + r_2 \)
9. if \( (R < r_2) \) \| \( (R \geq \text{Dv}) \) then \# (see Note 2)
   \( Q \leftarrow Q + 1 \) \# increment quotient
   \( R \leftarrow R - \text{Dv} \) \# decrement remainder

Assembler Code:

\[
\begin{align*}
# \text{Dh in r4, Dl in r5} \\
# \text{Dv in r6} \\
\text{divweu} \ r3, r4, r6 & \quad # q1 \\
\text{divwu} \ r7, r5, r6 & \quad # q2 \\
\text{mullw} \ r8, r3, r6 & \quad # -r1 = q1 \times \text{Dv} \\
\text{mullw} \ r0, r7, r6 & \quad # q2 \times \text{Dv} \\
\text{subf} \ r10, r0, r5 & \quad # r2 = \text{Dl} - (q2 \times \text{Dv}) \\
\text{add} \ r3, r3, r7 & \quad # Q = q1 + q2 \\
\text{subf} \ r4, r8, r10 & \quad # R = r1 + r2 \\
\text{cmplw} \ r4, r10 & \quad # R < r2 \quad ? \\
\text{blt} \ ^*+12 & \quad # \text{must adjust Q and R if yes} \\
\text{cmplw} \ r4, r6 & \quad # R \geq \text{Dv} \quad ? \\
\text{blt} \ ^*+12 & \quad # \text{must adjust Q and R if yes} \\
\text{addi} \ r3, r3, 1 & \quad # Q = Q + 1 \\
\text{subf} \ r4, r6, r4 & \quad # R = R - \text{Dv} \\
# \text{Quotient in r3} \\
# \text{Remainder in r4}
\end{align*}
\]

Notes:

1. The remainder is \( \text{Dh} \|^{320} (q_1 \times \text{Dv}) \). Because the remainder must be less than \( \text{Dv} \) and \( \text{Dv} < 2^{32} \), the remainder is representable in 32 bits. Because the low-order 32 bits of \( \text{Dh} \|^{320} \) are 0s, the remainder is therefore equal to the low-order 32 bits of \( -(q_1 \times \text{Dv}) \). Thus assigning \( -(q_1 \times \text{Dv}) \) to \( r1 \) yields the correct remainder.
2. \( R \) is less than \( r2 \) (and also less than \( r1 \)) if and only if the addition at step 6 carried out of 32 bits — i.e., if and only if the correct sum could not be represented in 32 bits — in which case the correct sum is necessarily greater than \( \text{Dv} \).
### 3.3.9.1 64-bit Fixed-Point Arithmetic Instructions [Category: 64-Bit]

#### Multiply Low Doubleword

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Format</th>
<th>64-bit Instruction</th>
<th>OE</th>
<th>RC</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td><code>mulldo</code></td>
<td>RT, RA, RB</td>
<td>(OE=1 RC=1)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

product:
```
prod0:127
```

The 64-bit operands are (RA) and (RB). The low-order 64 bits of the 128-bit product of the operands are placed into register RT.

If OE=1 then OV is set to 1 if the product cannot be represented in 64 bits.

Both operands and the product are interpreted as signed integers.

Special Registers Altered:
- CR0 (if RC=1)
- SO OV (if OE=1)

#### Programming Note

The XO-form `Multiply` instructions may execute faster on some implementations if RB contains the operand having the smaller absolute value.

#### Multiply High Doubleword

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Format</th>
<th>64-bit Instruction</th>
<th>RC</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mulhd</code></td>
<td>RT, RA, RB</td>
<td>(RC=0)</td>
<td></td>
</tr>
<tr>
<td><code>mulhd</code></td>
<td>RT, RA, RB</td>
<td>(RC=1)</td>
<td></td>
</tr>
</tbody>
</table>

product:
```
prod0:127 ← (RA) × (RB)
```

RT ← `prod0:63`

The 64-bit operands are (RA) and (RB). The high-order 64 bits of the 128-bit product of the operands are placed into register RT.

Both operands and the product are interpreted as signed integers.

Special Registers Altered:
- CR0 (if RC=1)

#### Multiply High Doubleword Unsigned

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Format</th>
<th>64-bit Instruction</th>
<th>RC</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mulhdu</code></td>
<td>RT, RA, RB</td>
<td>(RC=0)</td>
<td></td>
</tr>
<tr>
<td><code>mulhdu</code></td>
<td>RT, RA, RB</td>
<td>(RC=1)</td>
<td></td>
</tr>
</tbody>
</table>

product:
```
prod0:127 ← (RA) × (RB)
```

RT ← `prod0:63`

The 64-bit operands are (RA) and (RB). The high-order 64 bits of the 128-bit product of the operands are placed into register RT.

Both operands and the product are interpreted as unsigned integers, except that if RC=1 the first three bits of CR Field 0 are set by signed comparison of the result to zero.

Special Registers Altered:
- CR0 (if RC=1)
### Divide Doubleword

<table>
<thead>
<tr>
<th>Operation</th>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>divd</td>
<td>RT,RA,RB</td>
<td>(OE=0 Rc=0)</td>
</tr>
<tr>
<td>divd.</td>
<td>RT,RA,RB</td>
<td>(OE=0 Rc=1)</td>
</tr>
<tr>
<td>divdo</td>
<td>RT,RA,RB</td>
<td>(OE=1 Rc=0)</td>
</tr>
<tr>
<td>divdo.</td>
<td>RT,RA,RB</td>
<td>(OE=1 Rc=1)</td>
</tr>
</tbody>
</table>

Dividend0:63 \( \leftarrow (RA) \)

Divisor0:63 \( \leftarrow (RB) \)

The 64-bit dividend is \((RA)\). The 64-bit divisor is \((RB)\). The 64-bit quotient is placed into register RT. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as signed integers. The quotient is the unique signed integer that satisfies

\[
dividend = (\text{quotient} \times \text{divisor}) + r
\]

where \(0 \leq r < |\text{divisor}|\) if the dividend is nonnegative, and \(-|\text{divisor}| < r \leq 0\) if the dividend is negative.

If an attempt is made to perform any of the divisions

\[
0x8000_0000_0000_0000 \div \text{<anything>}
\]

then the contents of register RT are undefined as are \((\text{if Rc=1})\) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if OE=1 then OV is set to 1.

**Special Registers Altered:**

- CR0 (if Rc=1)
- SO OV (if OE=1)

### Programming Note

The 64-bit signed remainder of dividing \((RA)\) by \((RB)\) can be computed as follows, except in the case that \((RA) = -2^{63}\) and \((RB) = -1\).

<table>
<thead>
<tr>
<th>Operation</th>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>divd</td>

<tr>
<td>divduo</td>
<td>RT,RA,RB</td>
<td>(OE=1 Rc=0)</td>
</tr>
<tr>
<td>divduo.</td>
<td>RT,RA,RB</td>
<td>(OE=1 Rc=1)</td>
</tr>
</tbody>
</table>

Dividend0:63 \( \leftarrow (RA) \)

Divisor0:63 \( \leftarrow (RB) \)

The 64-bit dividend is \((RA)\). The 64-bit divisor is \((RB)\). The 64-bit quotient is placed into register RT. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as unsigned integers, except that if Rc=1 the first three bits of CR Field 0 are set by signed comparison of the result to zero. The quotient is the unique unsigned integer that satisfies

\[
dividend = (\text{quotient} \times \text{divisor}) + r
\]

where \(0 \leq r < \text{divisor}\).

If an attempt is made to perform the division

\[
\text{<anything>} \div 0
\]

then the contents of register RT are undefined as are \((\text{if Rc=1})\) the contents of the LT, GT, and EQ bits of CR Field 0. In this case, if OE=1 then OV is set to 1.

**Special Registers Altered:**

- CR0 (if Rc=1)
- SO OV (if OE=1)

### Programming Note

The 64-bit unsigned remainder of dividing \((RA)\) by \((RB)\) can be computed as follows.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>divdu</td>
<td>RT,RA,RB</td>
<td># RT = quotient</td>

divdeuo RT,RA,RB (OE=1 Rc=0)
divdeuo. RT,RA,RB (OE=1 Rc=1)

[Category: Server]
[Category: Embedded.Phased-In]

The 128-bit dividend is (RA) \| 640. The 64-bit divisor is (RB). If the quotient can be represented in 64 bits, it is placed into register RT. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as signed integers. The quotient is the unique signed integer that satisfies

\[
\text{dividend} = (\text{quotient} \times \text{divisor}) + r
\]

where \(0 \leq r < |\text{divisor}|\) if the dividend is nonnegative, and \(-|\text{divisor}| < r \leq 0\) if the dividend is negative.

If the quotient cannot be represented in 64 bits, or if an attempt is made to perform the division

\(<\text{anything}> \div 0\)

then the contents of register RT are undefined as are (if \(\text{Rc}=1\)) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if OE=1 then OV is set to 1.

Special Registers Altered:

<table>
<thead>
<tr>
<th>CR0</th>
<th>(if (\text{Rc}=1))</th>
</tr>
</thead>
<tbody>
<tr>
<td>SO</td>
<td>(if OE=1)</td>
</tr>
</tbody>
</table>

Programming Note

Unsigned long division of a 128-bit dividend contained in two 64-bit registers by a 64-bit divisor can be accomplished using the technique described in the Programming Note with the \texttt{divdeu} instruction description: \texttt{divdeu} would be used instead of \texttt{divweu} (and \texttt{cmpld} instead of \texttt{cmplw}, etc.).
3.3.10 Fixed-Point Compare Instructions

The fixed-point Compare instructions compare the contents of register RA with (1) the sign-extended value of the SI field, (2) the zero-extended value of the UI field, or (3) the contents of register RB. The comparison is signed for cmpi and cmp, and unsigned for cmpli and cmpl.

The L field controls whether the operands are treated as 64-bit or 32-bit quantities, as follows:

<table>
<thead>
<tr>
<th>L</th>
<th>Operand length</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>32-bit operands</td>
</tr>
<tr>
<td>1</td>
<td>64-bit operands</td>
</tr>
</tbody>
</table>

L=1 is part of Category: 64-Bit.

When the operands are treated as 32-bit signed quantities, bit 32 of the register (RA or RB) is the sign bit.

The Compare instructions set one bit in the leftmost three bits of the designated CR field to 1, and the other two to 0. XERSO is copied to bit 3 of the designated CR field.

The CR field is set as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>LT</td>
<td>(RA) &lt; SI or (RB) (signed comparison)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(RA) &lt; Ui or (RB) (unsigned comparison)</td>
</tr>
<tr>
<td>1</td>
<td>GT</td>
<td>(RA) &gt; SI or (RB) (signed comparison)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(RA) &gt; Ui or (RB) (unsigned comparison)</td>
</tr>
<tr>
<td>2</td>
<td>EQ</td>
<td>(RA) = SI, UI, or (RB)</td>
</tr>
<tr>
<td>3</td>
<td>SO</td>
<td>Summary Overflow from the XER</td>
</tr>
</tbody>
</table>

Extended mnemonics for compares

A set of extended mnemonics is provided so that compares can be coded with the operand length as part of the mnemonic rather than as a numeric operand. Some of these are shown as examples with the Compare instructions. See Appendix E for additional extended mnemonics.

### Compare Immediate

<table>
<thead>
<tr>
<th>Compare</th>
<th>BF,L,RA,SI</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmpli</td>
<td></td>
</tr>
<tr>
<td>cmpli</td>
<td></td>
</tr>
</tbody>
</table>

#### D-form

- **cmp**\(BF, L, RA, SI\)
- **cmp**\(BF, L, RA, SI\)

#### X-form

- **cmp**\(BF, L, RA, RB\)
- **cmp**\(BF, L, RA, RB\)

**Extended Mnemonics:**

**Example of extended mnemonics for Compare Immediate:**

<table>
<thead>
<tr>
<th>Extended</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmpli Rx,value</td>
<td>cmpl 0,Rx,value</td>
</tr>
<tr>
<td>cmpli cr3,Rx,value</td>
<td>cmpl 3,Rx,value</td>
</tr>
</tbody>
</table>

**Special Registers Altered:**

- CR field BF

**Extended Mnemonics:**

**Example of extended mnemonics for Compare:**

<table>
<thead>
<tr>
<th>Extended</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmpd Rx,Ry</td>
<td>cmp 0,Rx,Ry</td>
</tr>
<tr>
<td>cmplw cr3,Rx,Ry</td>
<td>cmpl 3,Rx,Ry</td>
</tr>
</tbody>
</table>
### Compare Logical Immediate

**D-form**

<table>
<thead>
<tr>
<th>cmpli</th>
<th>BF,L,RA,UI</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>6</td>
</tr>
<tr>
<td>8</td>
<td>L</td>
</tr>
<tr>
<td>10</td>
<td>RA</td>
</tr>
<tr>
<td>16</td>
<td>UI</td>
</tr>
<tr>
<td>31</td>
<td></td>
</tr>
</tbody>
</table>

if L = 0 then $a \leftarrow 32:0 || (RA)_{32:63}$
else $a \leftarrow (RA)$

if $a <_{u} (480 || UI)$ then $c \leftarrow 0b100$
else if $a >_{u} (480 || UI)$ then $c \leftarrow 0b010$
else $c \leftarrow 0b001$

$CR_{BF+32:4} \times BF+35 \leftarrow c || XERSO$

The contents of register RA ((RA)_{32:63} zero-extended to 64 bits if $L=0$) are compared with $480 || UI$, treating the operands as unsigned integers. The result of the comparison is placed into CR field BF.

**Special Registers Altered:**
CR field BF

**Extended Mnemonics:**

Examples of extended mnemonics for Compare Logical Immediate:

<table>
<thead>
<tr>
<th>Extended</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmpldi Nx.value</td>
<td>cmpl 0,1,Nx.value</td>
</tr>
<tr>
<td>cmplwi cr3,Nx.value</td>
<td>cmpl 3,0,Nx.value</td>
</tr>
</tbody>
</table>

**Compare Logical**

**X-form**

<table>
<thead>
<tr>
<th>cmpl</th>
<th>BF,L,RA,RB</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>8</td>
</tr>
<tr>
<td>9</td>
<td>L</td>
</tr>
<tr>
<td>11</td>
<td>RA</td>
</tr>
<tr>
<td>16</td>
<td>RB</td>
</tr>
<tr>
<td>21</td>
<td>32</td>
</tr>
<tr>
<td>31</td>
<td></td>
</tr>
</tbody>
</table>

if L = 0 then $a \leftarrow 32:0 || (RA)_{32:63}$
$b \leftarrow 32:0 || (RB)_{32:63}$
else $a \leftarrow (RA)$
$b \leftarrow (RB)$

if $a <_{u} b$ then $c \leftarrow 0b100$
else if $a >_{u} b$ then $c \leftarrow 0b010$
else $c \leftarrow 0b001$

$CR_{BF+32:4} \times BF+35 \leftarrow c || XERSO$

The contents of register RA ((RA)_{32:63} if $L=0$) are compared with the contents of register RB ((RB)_{32:63} if $L=0$), treating the operands as unsigned integers. The result of the comparison is placed into CR field BF.

**Special Registers Altered:**
CR field BF

**Extended Mnemonics:**

Examples of extended mnemonics for Compare Logical:

<table>
<thead>
<tr>
<th>Extended</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmpld Rx,Ry</td>
<td>cmpl 0,1,Rx,Ry</td>
</tr>
<tr>
<td>cmplw cr3,Rx,Ry</td>
<td>cmpl 3,0,Rx,Ry</td>
</tr>
</tbody>
</table>
3.3.11 Fixed-Point Trap Instructions

The Trap instructions are provided to test for a specified set of conditions. If any of the conditions tested by a Trap instruction are met, the system trap handler is invoked. If none of the tested conditions are met, instruction execution continues normally.

The contents of register RA are compared with either the sign-extended value of the SI field or the contents of register RB, depending on the Trap instruction. For tdi and td, the entire contents of RA (and RB) participate in the comparison; for twi and tw, only the contents of the low-order 32 bits of RA (and RB) participate in the comparison.

This comparison results in five conditions which are ANDed with TO. If the result is not 0 the system trap handler is invoked. These conditions are as follows.

<table>
<thead>
<tr>
<th>TO Bit</th>
<th>ANDed with Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Less Than, using signed comparison</td>
</tr>
<tr>
<td>1</td>
<td>Greater Than, using signed comparison</td>
</tr>
<tr>
<td>2</td>
<td>Equal</td>
</tr>
<tr>
<td>3</td>
<td>Less Than, using unsigned comparison</td>
</tr>
<tr>
<td>4</td>
<td>Greater Than, using unsigned comparison</td>
</tr>
</tbody>
</table>

Extended mnemonics for traps

A set of extended mnemonics is provided so that traps can be coded with the condition as part of the mnemonic rather than as a numeric operand. Some of these are shown as examples with the Trap instructions. See Appendix E for additional extended mnemonics.

<table>
<thead>
<tr>
<th>Trap Word Immediate</th>
<th>D-form</th>
<th>Trap Word X-form</th>
</tr>
</thead>
<tbody>
<tr>
<td>twi TO,RA,SI</td>
<td></td>
<td>tw TO,RA,RB</td>
</tr>
<tr>
<td>0 3 6 11 16 SI 31</td>
<td></td>
<td>0 31 6 11 16 21 31</td>
</tr>
<tr>
<td>a ← EXTS((RA)32:63)</td>
<td></td>
<td>a ← EXTS((RA)32:63)</td>
</tr>
<tr>
<td>if (a &lt; EXTS(SI)) &amp; TO0 then TRAP</td>
<td>b ← EXTS((RB)32:63)</td>
<td></td>
</tr>
<tr>
<td>if (a &gt; EXTS(SI)) &amp; TO1 then TRAP</td>
<td>if (a &lt; b) &amp; TO0 then TRAP</td>
<td></td>
</tr>
<tr>
<td>if (a = EXTS(SI)) &amp; TO2 then TRAP</td>
<td>if (a &gt; b) &amp; TO0 then TRAP</td>
<td></td>
</tr>
<tr>
<td>if (a &lt;u EXTS(SI)) &amp; TO3 then TRAP</td>
<td>if (a = b) &amp; TO2 then TRAP</td>
<td></td>
</tr>
<tr>
<td>if (a &gt;u EXTS(SI)) &amp; TO4 then TRAP</td>
<td>if (a &lt;u b) &amp; TO3 then TRAP</td>
<td></td>
</tr>
</tbody>
</table>

The contents of RA32:63 are compared with the sign-extended value of the SI field. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III).

Special Registers Altered: None

Extended Mnemonics:

**Trap Doubleword Immediate**  
**D-form**

\[
\text{tdi TO,RA,SI} \quad \text{SI} = 2^b \times (RA) + a
\]

The contents of register RA are compared with the sign-extended value of the SI field. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III).

**Special Registers Altered:**  
None

**Extended Mnemonics:**

Examples of extended mnemonics for **Trap Doubleword Immediate**:

- Extended: `tditi Rx,value`  
  Equivalent to: `tdi 16,Rx,value`
- Extended: `tdnei Rx,value`  
  Equivalent to: `tdi 24,Rx,value`

**Trap Doubleword**  
**X-form**

\[
\text{td TO,RA,RB} \quad \text{RB} = 2^c \times (RB) + b
\]

The contents of register RA are compared with the contents of register RB. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III).

**Special Registers Altered:**  
None

**Extended Mnemonics:**

Examples of extended mnemonics for **Trap Doubleword**:

- Extended: `tdge Rx,Ry`  
  Equivalent to: `td 12,Rx,Ry`

3.3.12 Fixed-Point Select [Category: Phased-In (sV2.06)]

**Integer Select**  
**A-form**

\[
isel RT,RA,RB,BC \quad \text{BC} = 2^d \times (RB) + c
\]

If the contents of bit BC+32 of the Condition Register are equal to 1, then the contents of register RA (or 0) are placed into register RT. Otherwise, the contents of register RB are placed into register RT.

**Special Registers Altered:**  
None

**Extended Mnemonics:**

Examples of extended mnemonics for **Integer Select**:

- Extended: `isellt Rx,Ry,Rz`  
  Equivalent to: `isel Rx,Ry,Rz,0`
- Extended: `iselgt Rx,Ry,Rz`  
  Equivalent to: `isel Rx,Ry,Rz,1`
- Extended: `iselleq Rx,Ry,Rz`  
  Equivalent to: `isel Rx,Ry,Rz,1`
3.3.13 Fixed-Point Logical Instructions

The Logical instructions perform bit-parallel operations on 64-bit operands.

The X-form Logical instructions with Rc=1, and the D-form Logical instructions andi. and andis., set the first three bits of CR Field 0 as described in Section 3.3.8, “Other Fixed-Point Instructions” on page 65. The Logical instructions do not change the SO, OV, and CA bits in the XER.

Extended mnemonics for logical operations

Extended mnemonics are provided that generate two different types of “no-ops” (instructions that do nothing). The first type is the preferred form, which is optimized to minimize its use of the processor’s execution resources. This form is based on the OR Immediate instruction. The second type is the executed form, which is intended to consume the same amount of the processor’s execution resources as if it were not a no-op. This form is based on the XOR Immediate instruction. (There are also no-ops that have other uses, such as affecting program priority, for which extended mnemonics have not been defined.)

Extended mnemonics are provided that use the OR and NOR instructions to copy the contents of one register to another, with and without complementing. These are shown as examples with the two instructions.

See Appendix E, “Assembler Extended Mnemonics” on page 709 for additional extended mnemonics.

---

**Programming Note**

Warning: Some forms of no-op may have side effects such as affecting program priority. Programmers should use the preferred no-op unless the side effects of some other form of no-op are intended.

---

**AND Immediate**  
D-form

<table>
<thead>
<tr>
<th>andi.</th>
<th>RA,RS,UI</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>0</th>
<th>28</th>
<th>RS</th>
<th>31</th>
</tr>
</thead>
</table>

RA ← (RS) & (480 || UI)

The contents of register RS are ANDed with 480 || UI and the result is placed into register RA.

**Special Registers Altered:**

CR0

**AND Immediate Shifted**  
D-form

<table>
<thead>
<tr>
<th>andis.</th>
<th>RA,RS,UI</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>0</th>
<th>29</th>
<th>RS</th>
<th>31</th>
</tr>
</thead>
</table>

RA ← (RS) & (320 || 160)

The contents of register RS are ANDed with 320 || 160 and the result is placed into register RA.

**Special Registers Altered:**

CR0

**OR Immediate**  
D-form

<table>
<thead>
<tr>
<th>ori</th>
<th>RA,RS,UI</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>0</th>
<th>24</th>
<th>RS</th>
<th>31</th>
</tr>
</thead>
</table>

RA ← (RS) | (480 || UI)

The contents of register RS are ORed with 480 || UI and the result is placed into register RA.

The preferred “no-op” (an instruction that does nothing) is:

ori 0,0,0

**Special Registers Altered:**

None

**Extended Mnemonics:**

Example of extended mnemonics for OR Immediate:

Extended:  
Equivalent to:

- no-op  
  ori 0,0,0
**OR Immediate Shifted**

**D-form**

\[ \text{oris} \quad \text{RA,RS,UI} \]

\[ \begin{array}{cccccc}
25 & 6 & 11 & 16 & 31 \\
\hline
\end{array} \]

\[ \text{RA} \leftarrow (\text{RS}) \mid (320 \mid \text{UI} \mid 160) \]

The contents of register RS are ORed with \(320 \parallel \text{UI} \parallel 160\) and the result is placed into register RA.

**Special Registers Altered:**

None

---

**XOR Immediate**

**D-form**

\[ \text{xori} \quad \text{RA,RS,UI} \]

\[ \begin{array}{cccccc}
26 & 6 & 11 & 16 & 31 \\
\hline
\end{array} \]

\[ \text{RA} \leftarrow (\text{RS}) \oplus (480 \mid \text{UI}) \]

The contents of register RS are XORed with \(480 \parallel \text{UI}\) and the result is placed into register RA.

The executed form of a “no-op” (an instruction that does nothing, but consumes execution resources nevertheless) is:

\[ \text{xori} \ 0,0,0 \]

**Special Registers Altered:**

None

**Extended Mnemonics:**

Example of extended mnemonics for **XOR Immediate**:

\[ \text{Extended: } \quad \text{Equivalent to:} \]

\[ \text{xnop} \quad \text{xori} \ 0,0,0 \]

---

**Programming Note**

The executed form of no-op should be used only when the intent is to alter the timing of a program.
**AND**

\[
\text{and} \quad \text{RA,RS,RB} \quad (\text{Rc}=0) \\
\text{and.} \quad \text{RA,RS,RB} \quad (\text{Rc}=1)
\]

\[
\begin{array}{cccccc}
31 & 6 & 11 & 16 & 21 & 28 \\
0 & 1 & 2 & 3 & 4 & 5
\end{array}
\]

RA \leftarrow (RS) \& (RB)

The contents of register RS are ANDed with the contents of register RB and the result is placed into register RA.

**X-form**

Some forms of **and** Rx, Rx, Rx may provide special functions, see Section 9.3 of Book III-S.

**Special Registers Altered:**

CR0 \hspace{1cm} (if Rc=1)

---

**OR**

\[
\text{or} \quad \text{RA,RS,RB} \quad (\text{Rc}=0) \\
\text{or.} \quad \text{RA,RS,RB} \quad (\text{Rc}=1)
\]

\[
\begin{array}{cccccc}
31 & 6 & 11 & 16 & 21 & 28 \\
0 & 1 & 2 & 3 & 4 & 5
\end{array}
\]

RA \leftarrow (RS) \oplus (RB)

The contents of register RS are XORed with the contents of register RB and the result is placed into register RA.

**X-form**

Some forms of **or** Rx,Rx,Rx provide special functions. See Section 3.2, ""or" Instruction", in Book II.

**Special Registers Altered:**

CR0 \hspace{1cm} (if Rc=1)

---

**NAND**

\[
\text{nand} \quad \text{RA,RS,RB} \quad (\text{Rc}=0) \\
\text{nand.} \quad \text{RA,RS,RB} \quad (\text{Rc}=1)
\]

\[
\begin{array}{cccccc}
31 & 6 & 11 & 16 & 21 & 28 \\
0 & 1 & 2 & 3 & 4 & 5
\end{array}
\]

RA \leftarrow \neg ((RS) \& (RB))

The contents of register RS are ANDed with the contents of register RB and the complemented result is placed into register RA.

**X-form**

**Special Registers Altered:**

CR0 \hspace{1cm} (if Rc=1)

---

**Programming Note**

**nand** or **nor** with RS=RB can be used to obtain the one's complement.
Chapter 3. Fixed-Point Facility

### NOR

**X-form**

nor    RA,RS,RB
nor.   RA,RS,RB

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>

<td>8</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The contents of register RS are ORed with the contents of register RB and the complemented result is placed into register RA.

**Special Registers Altered:**

CR0 (if Rc=1)

**Extended Mnemonics:**

Example of extended mnemonics for NOR:

<table>
<thead>
<tr>
<th>Extended:</th>
<th>Equivalent to:</th>
</tr>
</thead>
<tbody>
<tr>
<td>nor.</td>
<td>nor Rx, Ry</td>
</tr>
</tbody>
</table>

### AND with Complement

**X-form**

andc   RA,RS,RB
andc.  RA,RS,RB

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>

<td>8</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The contents of register RS are ANDed with the complement of the contents of register RB and the result is placed into register RA.

**Special Registers Altered:**

CR0 (if Rc=1)

The contents of register RS are XORed with the complement of the contents of register RB and the result is placed into register RA.

**Special Registers Altered:**

CR0 (if Rc=1)

### Extend Sign Byte

<table>
<thead>
<tr>
<th>Extendsb</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

s ← (RS)_{48}

RA_{48:63} ← (RS)_{48:63}

RA_{0:47} ← 48_{8}

(RS)_{48:63} are placed into RA_{48:63}. RA_{0:47} are filled with a copy of (RS)_{48}.

**Special Registers Altered:**

CR0 (if Rc=1)

### Count Leading Zeros Word

<table>
<thead>
<tr>
<th>Cntlzw</th>
<th>RA,RS</th>
</tr>
</thead>
<tbody>
<tr>
<td>cntlzw</td>
<td>RA,RS</td>
</tr>
</tbody>
</table>

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

Chapter 3. Fixed-Point Facility 85
cntlzwc. RA,RS (Rc=1)

\[
\begin{array}{cccccc}
31 & 30 & 29 & 28 & 27 & 26 & \text{Rc} \\
& & & & & & 31
\end{array}
\]

\[
\begin{array}{cccccc}
0 & 32 & 33 & 34 & 35 & 36 & 37
\end{array}
\]

\[
\text{n} \leftarrow 32 \\
\text{do while } n < 64 \\
\quad \text{if } (\text{RS})_n = 1 \text{ then leave} \\
\quad n \leftarrow n + 1 \\
\quad \text{RA} \leftarrow n - 32
\]

A count of the number of consecutive zero bits starting at bit 32 of register RS is placed into register RA. This number ranges from 0 to 32, inclusive.

If Rc=1, CR Field 0 is set to reflect the result.

**Special Registers Altered:**
CR0  
(if Rc=1)

**Programming Note**
For both *Count Leading Zeros* instructions, if Rc=1 then LT is set to 0 in CR Field 0.

### Compare Bytes

#### X-form

cmpb RA,RS,RB

\[
\begin{array}{cccccc}
31 & 30 & 29 & 28 & 27 & 26 & 25 \\
& & & & & & 31
\end{array}
\]

\[
\begin{array}{cccccc}
0 & 1 & 2 & 3 & 4 & 5 & 6
\end{array}
\]

\[
\text{do } n = 0 \text{ to } 7 \\
\quad \text{if } RS_{8\times n:8\times n+7} = (RB)_{8\times n:8\times n+7} \text{ then} \\
\quad \quad \text{RA}_{8\times n:8\times n+7} \leftarrow 1 \\
\quad \text{else} \\
\quad \quad \text{RA}_{8\times n:8\times n+7} \leftarrow 0
\]

Each byte of the contents of register RS is compared to each corresponding byte of the contents in register RB.

If they are equal, the corresponding byte in RA is set to 0xFF. Otherwise the corresponding byte in RA is set to 0x00.

**Special Registers Altered:**
None
### Population Count Bytes

**X-form**

<table>
<thead>
<tr>
<th>popcntb</th>
<th>RA, RS</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>8</td>
</tr>
</tbody>
</table>

```
\[
\begin{array}{llllll}
  & 31 & 8 & 11 & 16 & 21 & 122 \\
\end{array}
\]
```

```
do i = 0 to 7
  n ← 0
  do j = 0 to 7
    if (RS)(i×8)+j = 1 then
      n ← n+1
      RA(i×8):(i×8)+7 ← n
  RA[i×8]:[i×8]+7 ← n
```

A count of the number of one bits in each byte of register RS is placed into the corresponding byte of register RA. This number ranges from 0 to 8, inclusive.

**Special Registers Altered:**

None

### Population Count Words

**X-form**

<table>
<thead>
<tr>
<th>popcntw</th>
<th>RA, RS</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>8</td>
</tr>
</tbody>
</table>

```
\[
\begin{array}{llllll}
  & 31 & 8 & 11 & 16 & 21 & 378 \\
\end{array}
\]
```

```
do i = 0 to 1
  n ← 0
  do j = 0 to 31
    if (RS)(i×32)+j = 1 then
      n ← n+1
      RA(i×32):(i×32)+31 ← n
  RA[i×32]:[i×32]+31 ← n
```

A count of the number of one bits in each word of register RS is placed into the corresponding word of register RA. This number ranges from 0 to 32, inclusive.

**Special Registers Altered:**

None
Parity Doubleword

\texttt{prtyd \texttt{RA,RS}}

\hspace{1em} [Category: 64-bit]

<table>
<thead>
<tr>
<th>31</th>
<th>RS</th>
<th>RA</th>
<th>///</th>
<th>186</th>
<th>/</th>
</tr>
</thead>

\textbf{do} \ i = 0 \ \textbf{to} \ 3
\quad \textit{s} \leftarrow \textit{s} \oplus (\texttt{RS})_{16^7+7}
\textbf{do} \ i = 4 \ \textbf{to} \ 7
\quad \textit{t} \leftarrow \textit{t} \oplus (\texttt{RS})_{16^7+7}
\texttt{RA}_{0:31} \leftarrow 32\|\textit{s}
\texttt{RA}_{32:63} \leftarrow 32\|\textit{t}

The least significant bit in each byte of (\texttt{RS})_{0:31} is examined. If there is an odd number of one bits the value 1 is placed into \texttt{RA}_{0:31}; otherwise the value 0 is placed into \texttt{RA}_{0:31}. The least significant bit in each byte of (\texttt{RS})_{32:63} is examined. If there is an odd number of one bits the value 1 is placed into \texttt{RA}_{32:63}; otherwise the value 0 is placed into \texttt{RA}_{32:63}.

\textbf{Special Registers Altered:}

None

---

\textit{Programming Note}

The \textit{Parity} instructions are designed to be used in conjunction with the \textit{Population Count} instruction to compute the parity of words or a doubleword. The parity of the upper and lower words in (\texttt{RS}) can be computed as follows.

\texttt{popcntb RA, RS}
\texttt{prtyw RA, RA}

The parity of (\texttt{RS}) can be computed as follows.

\texttt{popcntb RA, RS}
\texttt{prtyd RA, RA}
### 3.3.13.1 64-bit Fixed-Point Logical Instructions [Category: 64-Bit]

\]

\[
RA \leftarrow n
\]

A count of the number of one bits in register RS is placed into register RA. This number ranges from 0 to 64, inclusive.

**Special Registers Altered:**

None
Bit Permute Doubleword  X-form

bpermd RA,RS,RB  
[Category: Embedded.Phased-in, Server]

|   | 31 | RS | RA | RB | 252 | /
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>31</td>
</tr>
</tbody>
</table>

For i = 0 to 7
  index ← (RS)8*i:8*i+7
  If index < 64
    then perm_i ← (RB)_{index}
    else perm_i ← 0
  RA ← 560 || perm0:7

Eight permuted bits are produced. For each permuted bit i where i ranges from 0 to 7 and for each byte i of RS, do the following.

  If byte i of RS is less than 64, permuted bit i is set to the bit of RB specified by byte i of RS; otherwise permuted bit i is set to 0.

The permuted bits are placed in the least-significant byte of RA, and the remaining bits are filled with 0s.

Special Registers Altered:
  None

Programming Note

The fact that the permuted bit is 0 if the corresponding index value exceeds 63 permits the permuted bits to be selected from a 128-bit quantity, using a single index register. For example, assume that the 128-bit quantity Q, from which the permuted bits are to be selected, is in registers r2 (high-order 64 bits of Q) and r3 (low-order 64 bits of Q), that the index values are in register r1, with each byte of r1 containing a value in the range 0:127, and that each byte of register r4 contains the value 64. The following code sequence selects eight permuted bits from Q and places them into the low-order byte of r6.

bpermd r6,r1,r2  # select from high-order half of Q
xor r0,r1,r4     # adjust index values
bpermd r5,r0,r3  # select from low-order half of Q
or r6,r6,r5      # merge the two selections
3.3.14 Fixed-Point Rotate and Shift Instructions

The Fixed-Point Facility performs rotation operations on data from a GPR and returns the result, or a portion of the result, to a GPR.

The rotation operations rotate a 64-bit quantity left by a specified number of bit positions. Bits that exit from position 0 enter at position 63.

Two types of rotation operation are supported.

For the first type, denoted rotate64 or ROTL64, the value rotated is the given 64-bit value. The rotate64 operation is used to rotate a given 64-bit quantity.

For the second type, denoted rotate32 or ROTL32, the value rotated consists of two copies of bits 32:63 of the given 64-bit value, one copy in bits 0:31 and the other in bits 32:63. The rotate32 operation is used to rotate a given 32-bit quantity.

The Rotate and Shift instructions employ a mask generator. The mask is 64 bits long, and consists of 1-bits from a start bit, mstart, through and including a stop bit, mstop, and 0-bits elsewhere. The values of mstart and mstop range from 0 to 63. If mstart > mstop, the 1-bits wrap around from position 63 to position 0. Thus the mask is formed as follows:

```
if mstart ≤ mstop then
    mask_mstart:mstop = ones
    mask_all other bits = zeros
else
    mask_mstart:63 = ones
    mask_0:mstop = ones
    mask_all other bits = zeros
```

There is no way to specify an all-zero mask.

For instructions that use the rotate32 operation, the mask start and stop positions are always in the low-order 32 bits of the mask.

The use of the mask is described in following sections.

The Rotate and Shift instructions with Rc=1 set the first three bits of CR field 0 as described in Section 3.3.8, “Other Fixed-Point Instructions” on page 65. Rotate and Shift instructions do not change the OV and SO bits. Rotate and Shift instructions, except algebraic right shifts, do not change the CA bit.

Extended mnemonics for rotates and shifts

The Rotate and Shift instructions, while powerful, can be complicated to code (they have up to five operands). A set of extended mnemonics is provided that allow simpler coding of often-used functions such as clearing the leftmost or rightmost bits of a register, left justifying or right justifying an arbitrary field, and performing simple rotates and shifts. Some of these are shown as examples with the Rotate instructions. See Appendix E, “Assembler Extended Mnemonics” on page 709 for additional extended mnemonics.

3.3.14.1 Fixed-Point Rotate Instructions

These instructions rotate the contents of a register. The result of the rotation is

- inserted into the target register under control of a mask (if a mask bit is 1 the associated bit of the rotated data is placed into the target register, and if the mask bit is 0 the associated bit in the target register remains unchanged); or

- ANDed with a mask before being placed into the target register.

The Rotate Left instructions allow right-rotation of the contents of a register to be performed (in concept) by a left-rotation of 64–n, where n is the number of bits by which to rotate right. They allow right-rotation of the contents of the low-order 32 bits of a register to be performed (in concept) by a left-rotation of 32–n, where n is the number of bits by which to rotate right.

The contents of register RS are rotated32 left SH bits. A mask is generated having 1-bits from bit MB+32 through bit ME+32 and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

Special Registers Altered:

CR0 (if Rc=1)
Extended Mnemonics:

Examples of extended mnemonics for Rotate Left Word Immediate then AND with Mask:

<table>

<td>rlwinm Rx,Ry,32-n,n,31</td>
</tr>
<tr>
<td>clrwi Rx,Ry,n</td>
<td>rlwinm Rx,Ry,0,0,31-n</td>
</tr>
</tbody>
</table>

Programming Note

Let RSL represent the low-order 32 bits of register RS, with the bits numbered from 0 through 31.

**rlwinm** can be used to extract an n-bit field that starts at bit position b in RSL, right-justified into the low-order 32 bits of register RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting SH=b, MB=32-n, and ME=31. It can be used to extract an n-bit field that starts at bit position b in RSL, left-justified into the low-order 32 bits of RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting SH=b, MB=0, and ME=n-1. It can be used to rotate the contents of the low-order 32 bits of a register left (right) by n bits, by setting SH=n bits, by setting SH=n (32-n), MB=0, and ME=31. It can be used to shift the contents of the low-order 32 bits of a register right by n bits, by setting SH=32-n, MB=0, and ME=31. It can be used to clear the high-order b bits of the low-order 32 bits of the contents of a register and then shift the result left by n bits, by setting SH=n, MB=b, and ME=31-n. It can be used to clear the low-order n bits of the low-order 32 bits of a register, by setting SH=0, MB=0, and ME=31-n. For all the uses given above, the high-order 32 bits of register RA are cleared.

Extended mnemonics are provided for all of these uses; see Appendix E, “Assembler Extended Mnemonics” on page 709.

Programming Note

Let RSL represent the low-order 32 bits of register RS, with the bits numbered from 0 through 31.

**rlwinm** can be used to extract an n-bit field that starts at variable bit position b in RSL, right-justified into the low-order 32 bits of register RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting RB_{59:63}=b, MB=32-n, and ME=31. It can be used to extract an n-bit field that starts at variable bit position b in RSL, left-justified into the low-order 32 bits of register RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting RB_{59:63}=b, MB=0, and ME=n-1. It can be used to rotate the contents of the low-order 32 bits of a register left (right) by variable n bits, by setting RB_{59:63}=n (32-n), MB=0, and ME=31. For all the uses given above, the high-order 32 bits of register RA are cleared.

Extended mnemonics are provided for some of these uses; see Appendix E, “Assembler Extended Mnemonics” on page 709.
Rotate Left Word Immediate then Mask Insert

\[ \text{rlwimi } RA,RS,SH,MB,ME \quad (Rc=0) \]

\[ \text{rlwimi. } RA,RS,SH,MB,ME \quad (Rc=1) \]

\[
\begin{array}{ccccccc}
20 & RS & RA & SH & MB & ME & Rc \\
0 & b & 11 & 16 & 21 & 26 & 31 \\
\end{array}
\]

\[
\begin{align*}
 n & \leftarrow SH \\
r & \leftarrow \text{ROTL}_{32}(\text{RS}_{32:63}, n) \\
m & \leftarrow \text{MASK}(MB+32, ME+32) \\
RA & \leftarrow r \& m \mid (RA) \& \neg m
\end{align*}
\]

The contents of register RS are rotated left SH bits. A mask is generated having 1-bits from bit MB+32 through bit ME+32 and 0-bits elsewhere. The rotated data are inserted into register RA under control of the generated mask.

Special Registers Altered:

CR0 \quad \text{(if } Rc=1) \]

Extended Mnemonics:

Example of extended mnemonics for Rotate Left Word Immediate then Mask Insert:

Extended: \hspace{1cm} Equivalent to:

\[
\begin{align*}
\text{inSlwi} & \quad Rx,Ry,n,b \quad \text{rlwimi } Rx,Ry,32-b,b,b+n-1
\end{align*}
\]

Programming Note

Let RAL represent the low-order 32 bits of register RA, with the bits numbered from 0 through 31.

\text{rlwimi} can be used to insert an n-bit field that is left-justified in the low-order 32 bits of register RS, into RAL starting at bit position b, by setting \( SH=32-b, MB=b, \) and \( ME=(b+n)-1 \). It can be used to insert an n-bit field that is right-justified in the low-order 32 bits of register RS, into RAL starting at bit position b, by setting \( SH=32-(b+n), MB=b, \) and \( ME=(b+n)-1 \).

Extended mnemonics are provided for both of these uses; see Appendix E, “Assembler Extended Mnemonics” on page 709.
3.3.14.1.1 64-bit Fixed-Point Rotate Instructions [Category: 64-Bit]

### Rotate Left Doubleword Immediate then Clear Left

<table>
<thead>
<tr>
<th>MD-form</th>
<th>RA,RS,SH,MB</th>
</tr>
</thead>
<tbody>
<tr>
<td>rldicl</td>
<td>(Rc=0)</td>

<td>31</td>
</tr>
</tbody>
</table>

\[
n \leftarrow sh_0 || sh_{0:4} \\
r \leftarrow \text{ROTL}_{64}((RS), n) \\
b \leftarrow mb_5 || mb_{0:4} \\
m \leftarrow \text{MASK}(b, 63) \\
RA \leftarrow r \& m
\]

The contents of register RS are rotated \(64\) left \(SH\) bits. A mask is generated having 1-bits from bit \(MB\) through bit 63 and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

**Special Registers Altered:**
- CR0 (if Rc=1)

**Extended Mnemonics:**

Examples of extended mnemonics for *Rotate Left Doubleword Immediate then Clear Left*:

- **Extended:**
  - extrdi Rx,Ry,n,b
  - srdi Rx,Ry,n
  - clrldi Rx,Ry,n

- **Equivalent to:**
  - rldicl Rx,Ry,b+n,64−n
  - rldicl Rx,Ry,64−n

**Programming Note**

*rldicl* can be used to extract an \(n\)-bit field that starts at bit position \(b\) in register RS, right-justified into register RA (clearing the remaining \(64−n\) bits of RA), by setting \(SH=b+n\) and \(MB=64−n\). It can be used to rotate the contents of a register left (right) by \(n\) bits, by setting \(SH=n\) (64−n) and \(MB=0\). It can be used to shift the contents of a register right by \(n\) bits, by setting \(SH=64−n\) and \(MB=n\). It can be used to clear the high-order \(n\) bits of a register, by setting \(SH=0\) and \(MB=n\).

Extended mnemonics are provided for all of these uses; see Appendix E, “Assembler Extended Mnemonics” on page 709.

### Rotate Left Doubleword Immediate then Clear Right

<table>
<thead>
<tr>
<th>MD-form</th>
<th>RA,RS,SH,ME</th>

m & \leftarrow \text{MASK}(b, \neg n) \\
RA & \leftarrow r \_ \& \_ m \_ (RA) \_ \& \_ \neg m
\end{align*}
\]

The contents of register RS are rotated left SH bits. A mask is generated having 1-bits from bit MB through bit 63-SH and 0-bits elsewhere. The rotated data are inserted into register RA under control of the generated mask.

**Special Registers Altered:**

- CR0

**Programming Note**

\textit{rldimi} can be used to insert an n-bit field that is right-justified in register RS, into register RA starting at bit position b, by setting SH=64-(b+n) and MB=b.

An extended mnemonic is provided for this use; see Appendix E, “Assembler Extended Mnemonics” on page 709.
3.3.14.2 Fixed-Point Shift Instructions

The instructions in this section perform left and right shifts.

**Extended mnemonics for shifts**

Immediate-form logical (unsigned) shift operations are obtained by specifying appropriate masks and shift values for certain *Rotate* instructions. A set of extended mnemonics is provided to make coding of such shifts simpler and easier to understand. Some of these are shown as examples with the *Rotate* instructions. See Appendix E, “Assembler Extended Mnemonics” on page 709 for additional extended mnemonics.

---

**Programming Note**

Any Shift Right Algebraic instruction, followed by *addze*, can be used to divide quickly by $2^n$. The setting of the CA bit by the Shift Right Algebraic instructions is independent of mode.

**Programming Note**

Multiple-precision shifts can be programmed as shown in Section F.1, “Multiple-Precision Shifts” on page 723.

---

### Shift Left Word

**X-form**

\[

\( r \leftarrow \text{ROTL}_{32}((RS)_{32:63}, 64-n) \)

\( m \leftarrow \text{MASK}(n+32, 63) \)

\( s \leftarrow (RS)_{32} \)

\( RA \leftarrow r \& m \mid (64s)\&\neg m \)

\( CA \leftarrow s \& ((r\&\neg m)_{32:63}\neq 0) \)

The contents of the low-order 32 bits of register RS are shifted right \( SH \) bits. Bits shifted out of position 63 are lost. Bit 32 of RS is replicated to fill the vacated positions on the left. The 32-bit result is placed into RA\(_{32:63}\). Bit 32 of RS is replicated to fill RA\(_{0:31}\). CA is set to 0 if the low-order 32 bits of (RS) contain a negative number and any 1-bits are shifted out of position 63; otherwise CA is set to 0. A shift amount of zero causes RA to receive EXTS((RS)\(_{32:63}\)), and CA to be set to 0.

**Special Registers Altered:**

- CA

The contents of register RS are shifted right the number of bits specified by \((\text{RB})_{57:63}\). Bits shifted out of position 63 are lost. Bit 0 of RS is replicated to fill the vacated positions on the left. The result is placed into register RA. CA is set to 1 if (RS) is negative and any 1-bits are shifted out of position 63; otherwise CA is set to 0. A shift amount of zero causes RA to be set equal to (RS), and CA to be set to 0. Shift amounts from 64 to 127 give a result of 64 sign bits in RA, and cause CA to receive the sign bit of (RS).

**Special Registers Altered:**
- \(\text{CA}\)
- \(\text{CR0}\) (if Rc=1)
3.3.15 Binary Coded Decimal (BCD) Assist Instructions [Category: Embedded.Phased-in, Server]

The Binary Coded Decimal Assist instructions operate on Binary Coded Decimal operands (cbcdtd and cdbcd) and Decimal Floating-Point operands (cdt-bcd) See Chapter 6. for additional information.

**Convert Declets To Binary Coded Decimal X-form**

```
cdbcd RA, RS

<table>
<thead>
<tr>
<th>31</th>
<th>RS</th>
<th>RA</th>
<th>--</th>
<th>282</th>
<th>--</th>
</tr>
</thead>
</table>
```

`do i = 0 to 1
n ← i x 32
RA_{n+0:n+7} ← 0
RA_{n+8:n+19} ← DPD_TO_BCD( (RS)_{n+12:n+21} )
RA_{n+20:n+31} ← DPD_TO_BCD( (RS)_{n+22:n+31} )`

The low-order 20 bits of each word of register RS contain two declets which are converted to six, 4-bit BCD fields; each set of six, 4-bit BCD fields is placed into the low-order 24 bits of the corresponding word in RA. The high-order 8 bits in each word of RA are set to 0.

**Special Registers Altered:**
None

**Convert Binary Coded Decimal To Declets X-form**

```
ccbddd RA, RS

<table>
<thead>
<tr>
<th>31</th>
<th>RS</th>
<th>RA</th>
<th>--</th>
<th>314</th>
<th>--</th>
</tr>
</thead>
</table>
```

`do i = 0 to 1
n ← i x 32
RA_{n+0:n+11} ← 0
RA_{n+12:n+21} ← BCD_TO_DPD( (RS)_{n+8:n+19} )
RA_{n+22:n+31} ← BCD_TO_DPD( (RS)_{n+20:n+31} )`

The low-order 24 bits of each word of register RS contain six, 4-bit BCD fields which are converted to two declets; each set of two declets is placed into the low-order 20 bits of the corresponding word in RA. The high-order 12 bits in each word of RA are set to 0.

**Special Registers Altered:**
None

**Add and Generate Sixes XO-form**

```
addg6s RT,RA,RB

<table>
<thead>
<tr>
<th>31</th>
<th>RT</th>
<th>RA</th>
<th>RB</th>
<th>--</th>
<th>74</th>
<th>--</th>
</tr>
</thead>
</table>
```

`do i = 0 to 15
dc_i ← carry_out( RA_{4xi:63} + RB_{4xi:63} )
c ← 4(dc_0) || 4(dc_1) || ... || 4(dc_{15})
RT ← (¬c) & 0x6666_6666_6666_6666`

The contents of register RA are added to the contents of register RB. Sixteen carry bits are produced, one for each carry out of decimal position n (bit position 4xn).

A doubleword is composed from the 16 carry bits, and placed into RT. The doubleword consists of a decimal six (0b0110) in every decimal digit position for which the corresponding carry bit is 0, and a zero (0b0000) in every position for which the corresponding carry bit is 1.

**Special Registers Altered:**
None

addg6s can be used to add or subtract two BCD operands. In these examples it is assumed that r0 contains 0x666...666. (BCD data formats are described in Section 6.3.)

Addition of the unsigned BCD operand in register RA to the unsigned BCD operand in register RB can be accomplished as follows.

\[
\begin{align*}
\text{add} & \quad r1, RA, r0 \\
\text{add} & \quad r2, r1, RB \\
\text{addg6s} & \quad RT, r1, RB \\
\text{subf} & \quad RT, RT, r2 \# RT = RA \times_{BCD} RB
\end{align*}
\]

Subtraction of the unsigned BCD operand in register RA from the unsigned BCD operand in register RB can be accomplished as follows. (In this example it is assumed that RB is not register 0.)

\[
\begin{align*}
\text{addi} & \quad r1, RB, 1 \\
\text{nor} & \quad r2, RA, RA \# \text{one's complement of RA} \\
\text{add} & \quad r3, r1, r2 \\
\text{addg6s} & \quad RT, r1, r2 \\
\text{subf} & \quad RT, RT, r3 \# RT = RB -_{BCD} RA
\end{align*}
\]

Additional instructions are needed to handle signed BCD operands, and BCD operands that occupy more than one register (e.g., unsigned BCD operands that have more than 16 decimal digits).
3.3.16 Move To/From System Register Instructions

The *Move To Condition Register Fields* instruction has a preferred form; see Section 1.8.1, "Preferred Instruction Forms" on page 22. In the preferred form, the FXM field satisfies the following rule:

- Exactly one bit of the FXM field is set to 1.

**Extended mnemonics**

Extended mnemonics are provided for the *mtspr* and *mfspr* instructions so that they can be coded with the SPR name as part of the mnemonic rather than as a numeric operand. An extended mnemonic is provided for the *mtcrf* instruction for compatibility with old software (written for a version of the architecture that precedes Version 2.00) that uses it to set the entire Condition Register. Some of these extended mnemonics are shown as examples with the relevant instructions. See Appendix E, "Assembler Extended Mnemonics" on page 709 for additional extended mnemonics.
Move To Special Purpose Register
XFX-form

mtspr SPR,RS

\[
\begin{array}{cccc}
\text{decimal} & \text{SPR}^1 spr_{5:9} & \text{SPR}_{0:4} & \text{Name} \\

771 & 11000 00011 & MMCRA^3 & \\
\hline
\end{array}
\]

1. Note that the order of the two 5-bit halves of the SPR number is reversed.
2. Category: SPE.
3. Category: Server; see Book III-S.
4. Category: Transactional Memory. See Chapter 5 of Book II.
5. Category: Stream.
6. Accesses to these registers are noops; see Section 1.3.3, “Reserved Fields, Reserved Values, and Reserved SPRs”
7. Category: Server; see Book II.
8. Accesses to these registers are noops; see Section 1.3.3, “Reserved Fields, Reserved Values, and Reserved SPRs”
9. Category: Server; see Book II.

If execution of this instruction is attempted specifying an SPR number that is not shown above, or an SPR number that is shown above but is in a category that is not supported by the implementation, one of the following occurs:

- If spr0 = 0, the illegal instruction error handler is invoked.
- If spr0 = 1, the system privileged instruction error handler is invoked.

If an attempt is made to execute \texttt{mtspr} specifying a TM SPR in other than Non-Transactional state, a TM Bad Thing type Program interrupt is generated.

A complete description of this instruction can be found in Book III.

Special Registers Altered:

See above

Extended Mnemonics:

Examples of extended mnemonics for \texttt{Move To Special Purpose Register}:

\[
\begin{array}{ll}
\text{Extended} & \text{Equivalent to} \\
\texttt{mtxer} Rx & \texttt{mtspr} 1,Rx \\
\texttt{mtlr} Rx & \texttt{mtspr} 8,Rx \\
\end{array}
\]
Extended:               Equivalent to:
mtctr    Rx               mtspr   9,Rx
mtppr    Rx               mtspr  896,Rx
mtppr32  Rx               mtspr  898,Rx

--- Programming Note ---
The AMR is part of the “context” of the program  
(see Book III-S).  Therefore modification of the AMR  
requires “synchronization” by software.  For this rea-  
son, most operating systems provide a system  
library program that application programs can use  
to modify the AMR.

--- Compiler and Assembler Note ---
For the mtspr and mfspr instructions, the SPR  
number coded in Assembler language does not  
appear directly as a 10-bit binary number in the  
instruction. The number coded is split into two 5-bit  
halves that are reversed in the instruction, with the  
high-order 5 bits appearing in bits 16:20 of the  
instruction and the low-order 5 bits in bits 11:15.
Move From Special Purpose Register

**XFX-form**

```markdown
mfspr  RT,SPR
```

```markdown
n <- spr5:9 || spr0:4
switch (n)
  case(129): see Book III-S
  case(808, 809, 810, 811):
    default:
      if length(SPR[n]) = 64 then
        RT <- SPR[n]
      else
        RT <- 32
        SPRT[n]
```

The SPR field denotes a Special Purpose Register, encoded as shown in the table below. If the SPR field contains 129, the instruction references the Transaction Failure Instruction Address Register (TFIAR) and the result is dependent on the privilege with which it is executed. See Book III-S. If the SPR field contains a value from 808 through 811, the instruction specifies a reserved SPR, and is treated as a noop; see Section 1.3.3, “Reserved Fields, Reserved Values, and Reserved SPRs”. Otherwise, the contents of the designated Special Purpose Register are placed into register RT. For Special Purpose Registers that are 32 bits long, the low-order 32 bits of RT receive the contents of the Special Purpose Register and the high-order 32 bits of RT are set to zero.

![Register Name Table]

### Note
1. Note that the order of the two 5-bit halves of the SPR number is reversed.
2. Category: Embedded.
3. See Chapter 6 of Book II.
4. Category: SPE.
6. Category: Server; see Book III-S.
7. Category: Transactional Memory. See Chapter 5 of Book II.
9. Accesses to these SPRs are noops; see Section 1.3.3, “Reserved Fields, Reserved Values, and Reserved SPRs”.
10. Category: Server; see Book II.

If execution of this instruction is attempted specifying an SPR number that is not shown above, or an SPR number that is shown above but is in a category that is not supported by the implementation, one of the following occurs.
If spr0 = 0, the illegal instruction error handler is invoked.
If spr0 = 1, the system privileged instruction error handler is invoked.

A complete description of this instruction can be found in Book III.

**Special Registers Altered:**
None

**Extended Mnemonics:**
Examples of extended mnemonics for Move From Special Purpose Register:

<table>
<thead>
<tr>
<th>Extended:</th>
<th>Equivalent to:</th>
</tr>
</thead>
<tbody>
<tr>
<td>mfxer Rx</td>
<td>mfspr Rx,1</td>
</tr>
<tr>
<td>mflr Rx</td>
<td>mfspr Rx,8</td>
</tr>
<tr>
<td>mfctr Rx</td>
<td>mfspr Rx,9</td>
</tr>
</tbody>
</table>

**Note**
See the Notes that appear with mtspcr.

*Move To Condition Register Fields*

**XFX-form**

```plaintext
mtcrf FXM,RS
```

<table>
<thead>
<tr>
<th>31</th>
<th>RS</th>
<th>0</th>
<th>FXM</th>
<th>/</th>
<th>144</th>
<th>/</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td>11</td>
<td>2</td>
<td></td>
<td>20</td>
<td>21</td>
<td></td>
</tr>
</tbody>
</table>

mask = 4(FXM0) || 4(FXM1) || ... 4(FXM7)
CR = ((RS)32:63 & mask) | (CR & ¬mask)

The contents of bits 32:63 of register RS are placed into the Condition Register under control of the field mask specified by FXM. The field mask identifies the 4-bit fields affected. Let i be an integer in the range 0-7. If FXMi=1 then CR field i (CR bits 4×i+32:4×i+35) is set to the contents of the corresponding field of the low-order 32 bits of RS.

**Special Registers Altered:**
CR fields selected by mask

**Extended Mnemonics:**
Example of extended mnemonics for *Move To Condition Register Fields*:

<table>
<thead>
<tr>
<th>Extended:</th>
<th>Equivalent to:</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtcrr Rx</td>
<td>mtcrr 0xFF,Rx</td>
</tr>
</tbody>
</table>

**Programming Note**
In the preferred form of this instruction (*mtocrf*), only one Condition Register field is updated.
### Move From Condition Register  XFX-form

**mfcr RT**

| 0 | 31 | 6 | 11 | 12 | 21 | 19 | 31 |

RT ← \(32 \_0 | CR\)

The contents of the Condition Register are placed into RT\(_{32:63}\). RT\(_{0:31}\) are set to 0.

**Special Registers Altered:**

None

### Move To Split Little Endian  X-form

**mtsle L**

[Category: Server]

| 31 | /// | L | /// | /// | 147 |

SLE ← L

The value specified in the L field is placed into SLE.

**L=0**

SLE is set to 0. The Endian mode used for both data and instruction storage accesses is represented by the value specified by LE.

**L=1**

SLE is set to 1. The Endian mode used for instruction storage accesses is represented by the value of LE. The Endian mode used for data storage accesses is represented by the value of ¬LE.

The effects of executing **mtsle** are immediately effective for subsequent storage accesses.

**Special Registers Altered:**

**Special Registers Altered:**  
CR field selected by FXM

**Programming Note**

These forms of the `mtocrf` and `mfocrf` instructions are intended to replace the old forms of the instructions (the forms shown in page 107), which will eventually be phased out of the architecture. The new forms are backward compatible with most processors that comply with versions of the architecture that precede Version 2.00. On those processors, the new forms are treated as the old forms.

However, on some processors that comply with versions of the architecture that precede Version 2.00 the new forms may be treated as follows:

- **mtocrf:** may cause the system illegal instruction error handler to be invoked
- **mfocrf:** may place an undefined value into register RT

Chapter 4. Floating-Point Facility [Category: Floating-Point]

4.1 Floating-Point Facility Overview

This chapter describes the registers and instructions that make up the Floating-Point Facility.

The processor (augmented by appropriate software support, where required) implements a floating-point system compliant with the ANSI/IEEE Standard 754-1985, “IEEE Standard for Binary Floating-Point Arithmetic” (hereafter referred to as “the IEEE standard”). That standard defines certain required "operations" (addition, subtraction, etc.). Herein, the term “floating-point operation" is used to refer to one of these required operations and to additional operations defined (e.g., those performed by Multiply-Add or Reciprocal Estimate instructions). A Non-IEEE mode is also provided. This mode, which may produce results not in strict compliance with the IEEE standard, allows shorter latency.

Instructions are provided to perform arithmetic, rounding, conversion, comparison, and other operations in floating-point registers; to move floating-point data between storage and these registers; and to manipulate the Floating-Point Status and Control Register explicitly.

These instructions are divided into two categories:

- computational instructions
  
The computational instructions are those that perform addition, subtraction, multiplication, division, extracting the square root, rounding, conversion, comparison, and combinations of these operations. These instructions provide the floating-point operations. They place status information into the Floating-Point Status and Control Register. They are the instructions described in Sections 4.6.6 through 4.6.8.

- non-computational instructions
  
The non-computational instructions are those that perform loads and stores, move the contents of a floating-point register to another floating-point register possibly altering the sign, manipulate the Floating-Point Status and Control Register explicitly, and select the value from one of two floating-point registers based on the value in a third floating-point register. The operations performed by these instructions are not considered floating-point operations. With the exception of the instructions that manipulate the Floating-Point Status and Control Register explicitly, they do not alter the Floating-Point Status and Control Register. They are the instructions described in Sections 4.6.2 through 4.6.5, and 4.6.10.

A floating-point number consists of a signed exponent and a signed significand. The quantity expressed by this number is the product of the significand and the number $2^{exponent}$. Encodings are provided in the data format to represent finite numeric values, $\pm\infty$, and values that are “Not a Number” (NaN). Operations involving infinities produce results obeying traditional mathematical conventions. NaNs have no mathematical interpretation. Their encoding permits a variable diagnostic information field. They may be used to indicate such things as uninitialized variables and can be produced by certain invalid operations.

There is one class of exceptional events that occur during instruction execution that is unique to the Floating-Point Facility: the Floating-Point Exception. Floating-point exceptions are signaled with bits set in the Floating-Point Status and Control Register (FPSCR). They can cause the system floating-point enabled exception error handler to be invoked, precisely or imprecisely, if the proper control bits are set.

Floating-Point Exceptions

The following floating-point exceptions are detected by the processor:

- Invalid Operation Exception (VX)
  - SNaN (VXSNAN)
  - Infinity--Infinity (VXSI)
  - Infinity--Infinity (VXID)
  - Zero--Zero (VXZDZ)
  - Infinity--Zero (VXIMZ)
  - Invalid Compare (VXVC)
  - Software-Defined Condition (VXSOFT)
  - Invalid Square Root (VXSQRT)
Each floating-point exception, and each category of invalid operation exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. See Section 4.2.2, “Floating-Point Status and Control Register” on page 116 for a description of these exception and enable bits, and Section 4.4, “Floating-Point Exceptions” on page 124 for a detailed discussion of floating-point exceptions, including the effects of the enable bits.

4.2 Floating-Point Facility Registers

4.2.1 Floating-Point Registers

Implementations of this architecture provide 32 floating-point registers (FPRs). The floating-point instruction formats provide 5-bit fields for specifying the FPRs to be used in the execution of the instruction. The FPRs are numbered 0-31. See Figure 50 on page 116.

Each FPR contains 64 bits that support the floating-point double format. Every instruction that interprets the contents of an FPR as a floating-point value uses the floating-point double format for this interpretation.

The computational instructions, and the Move and Select instructions, operate on data located in FPRs and, with the exception of the Compare instructions, place the result value into an FPR and optionally (when Rc=1) place status information into the Condition Register. Instruction forms with Rc=1 are part of Category: Floating-Point.Record.

Load Double and Store Double instructions are provided that transfer 64 bits of data between storage and the FPRs with no conversion. Load Single instructions are provided to transfer and convert floating-point values in floating-point single format from storage to the same value in floating-point double format in the FPRs. Store Single instructions are provided to transfer and convert floating-point values in floating-point double format from the FPRs to the same value in floating-point single format in storage.

Instructions are provided that manipulate the Floating-Point Status and Control Register and the Condition Register explicitly. Some of these instructions copy data from an FPR to the Floating-Point Status and Control Register or vice versa.

The computational instructions and the Select instruction accept values from the FPRs in double format. For single-precision arithmetic instructions, all input values must be representable in single format; if they are not, the result placed into the target FPR, and the setting of status bits in the FPSCR and in the Condition Register (if Rc=1), are undefined.

4.2.2 Floating-Point Status and Control Register

The Floating-Point Status and Control Register (FPSCR) controls the handling of floating-point exceptions and records status resulting from the floating-point operations. Bits 32:55 are status bits. Bits 56:63 are control bits.

The exception bits in the FPSCR (bits 35:44, 53:55) are sticky; that is, once set to 1 they remain set to 1 until they are set to 0 by an \texttt{mcrfs}, \texttt{mtfsfi}, \texttt{mtfsf}, or \texttt{mtfsb0} instruction. The exception summary bits in the FPSCR (FX, FEX, and VX, which are bits 32:34) are not considered to be “exception bits”, and only FX is sticky.

FEX and VX are simply the ORs of other FPSCR bits. Therefore these two bits are not listed among the FPSCR bits affected by the various instructions.

Hypothetical example table:

<table>
<thead>
<tr>
<th>Bit(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0:31</td>
<td>Reserved</td>
</tr>
<tr>
<td>32</td>
<td>Floating-Point Exception Summary (FX)</td>
</tr>
</tbody>
</table>

Every floating-point instruction, except \texttt{mtfsfi} and \texttt{mtfsf}, implicitly sets FPSCR\textsubscript{FX} to 1 if that instruction causes any of the floating-point exception bits in the FPSCR to change from 0 to 1. \texttt{mcrfs}, \texttt{mtfsfi}, \texttt{mtfsf}, \texttt{mtfsb0}, and \texttt{mtfsb1} can alter FPSCR\textsubscript{FX} explicitly.
Floating-Point Enabled Exception Summary (FEX)
This bit is the OR of all the floating-point exception bits masked by their respective enable bits. `mcrfs`, `mtfsfi`, `mtfsf`, `mtfsb0`, and `mtfsb1` cannot alter FPSCR_FEX explicitly.

Floating-Point Invalid Operation Exception Summary (VX)
This bit is the OR of all the Invalid Operation exception bits. `mcrfs`, `mtfsfi`, `mtfsf`, `mtfsb0`, and `mtfsb1` cannot alter FPSCR_VX explicitly.

Floating-Point Overflow Exception (OX)
See Section 4.4.3, “Overflow Exception” on page 127.

Floating-Point Underflow Exception (UX)
See Section 4.4.4, “Underflow Exception” on page 128.

Floating-Point Zero Divide Exception (ZX)
See Section 4.4.2, “Zero Divide Exception” on page 126.

Floating-Point Inexact Exception (XX)
See Section 4.4.5, “Inexact Exception” on page 128.

Floating-Point Fraction Rounded (FR)
The last Arithmetic or Rounding and Conversion instruction incremented the fraction during rounding. See Section 4.3.6, “Rounding” on page 123. This bit is not sticky.

Floating-Point Fraction Inexact (FI)
The last Arithmetic or Rounding and Conversion instruction either produced an inexact result during rounding or caused a disabled Overflow Exception. See Section 4.3.6. This bit is not sticky.

Floating-Point Result Flags (FPRF)
Arithmetic, rounding, and Convert From Integer instructions set this field based on the result placed into the target register and on the target precision, except that if any portion of the result is undefined then the value placed into FPRF is undefined. Floating-point Compare instructions set this field based on the relative values of the operands being compared. For Convert To Integer instructions, the value placed into FPRF is undefined. Additional details are given below.

Floating-Point Result Class Descriptor (C)
Arithmetic, rounding, and Convert From Integer instructions may set this bit with the FPCC bits, to indicate the class of the result as shown in Figure 52 on page 119.

Floating-Point Condition Code (FPCC)
Floating-point Compare instructions set one of

Programming Note

A single-precision operation that produces a denormalized result sets FPRF to indicate a denormalized number. When possible, single-precision denormalized numbers are represented in normalized double format in the target register.

Floating-Point Invalid Operation Exception ($\infty \div \infty$) (VXIDI)
See Section 4.4.1.

Floating-Point Invalid Operation Exception (0 \cdot 0) (VXZDZ)
See Section 4.4.1.

Floating-Point Invalid Operation Exception ($\infty \cdot 0$) (VXIMZ)
See Section 4.4.1.

Floating-Point Invalid Operation Exception (Invalid Compare) (VXVC)
See Section 4.4.1.

Floating-Point Fraction Rounded (FR)
The last Arithmetic or Rounding and Conversion instruction incremented the fraction during rounding. See Section 4.3.6, “Rounding” on page 123. This bit is not sticky.

Floating-Point Fraction Inexact (FI)
The last Arithmetic or Rounding and Conversion instruction either produced an inexact result during rounding or caused a disabled Overflow Exception. See Section 4.3.6. This bit is not sticky.

See the definition of FPSCR_VX, above, regarding the relationship between FPSCR_FI and FPSCR_VX.

Floating-Point Result Flags (FPRF)
Arithmetic, rounding, and Convert From Integer instructions set this field based on the result placed into the target register and on the target precision, except that if any portion of the result is undefined then the value placed into FPRF is undefined. Floating-point Compare instructions set this field based on the relative values of the operands being compared. For Convert To Integer instructions, the value placed into FPRF is undefined. Additional details are given below.

Floating-Point Result Class Descriptor (C)
Arithmetic, rounding, and Convert From Integer instructions may set this bit with the FPCC bits, to indicate the class of the result as shown in Figure 52 on page 119.

Floating-Point Condition Code (FPCC)
Floating-point Compare instructions set one of

Programming Note

A single-precision operation that produces a denormalized result sets FPRF to indicate a denormalized number. When possible, single-precision denormalized numbers are represented in normalized double format in the target register.
the FPCC bits to 1 and the other three FPCC bits to 0. Arithmetic, rounding, and Convert From Integer instructions may set the FPCC bits with the C bit, to indicate the class of the result as shown in Figure 52 on page 119. Note that in this case the high-order three bits of the FPCC retain their relational significance indicating that the value is less than, greater than, or equal to zero.

**Floating-Point Less Than or Negative** (FL or \(<\))

**Floating-Point Greater Than or Positive** (FG or \(>\))

**Floating-Point Equal or Zero** (FE or \(=\))

**Floating-Point Unordered or NaN** (FU or \(?\))

**Floating-Point Invalid Operation Exception (Software-Defined Condition)** (VXSOFT)

This bit can be altered only by `mcrfs`, `mtfsfi`, `mtfsf`, `mtfsb0`, or `mtfsb1`. See Section 4.4.1.

**Programming Note**

FPSCR\(_{VXSOFT}\) can be used by software to indicate the occurrence of an arbitrary, software-defined, condition that is to be treated as an Invalid Operation Exception. For example, the bit could be set by a program that computes a base 10 logarithm if the supplied input is negative.

**Floating-Point Invalid Operation Exception (Invalid Square Root)** (VXSQRT)

See Section 4.4.1.

**Floating-Point Invalid Operation Exception (Invalid Integer Convert)** (VXCVI)

See Section 4.4.1.

**Floating-Point Invalid Operation Exception Enable** (VE)

See Section 4.4.1.

**Floating-Point Overflow Exception Enable** (OE)

See Section 4.4.3, “Overflow Exception” on page 127.

**Floating-Point Underflow Exception Enable** (UE)

See Section 4.4.4, “Underflow Exception” on page 128.

**Floating-Point Zero Divide Exception Enable** (ZE)

See Section 4.4.2, “Zero Divide Exception” on page 126.

**Floating-Point Inexact Exception Enable** (XE)

See Section 4.4.5, “Inexact Exception” on page 128.

**Floating-Point Non-IEEE Mode** (NI)

Floating-point non-IEEE mode is optional. If floating-point non-IEEE mode is not implemented, this bit is treated as reserved, and the remainder of the definition of this bit does not apply.

If floating-point non-IEEE mode is implemented, this bit has the following meaning.

0 The processor is not in floating-point non-IEEE mode (i.e., all floating-point operations conform to the IEEE standard).

1 The processor is in floating-point non-IEEE mode.

When the processor is in floating-point non-IEEE mode, the remaining FPSCR bits may have meanings different from those given in this document, and floating-point operations need not conform to the IEEE standard. The effects of executing a given floating-point instruction with FPSCR\(_{NI}=1\), and any additional requirements for using non-IEEE mode, are implementation-dependent. The results of executing a given instruction in non-IEEE mode may vary between implementations, and between different executions on the same implementation.

**Programming Note**

When the processor is in floating-point non-IEEE mode, the results of floating-point operations may be approximate, and performance for these operations may be better, more predictable, or less data-dependent than when the processor is not in non-IEEE mode. For example, in non-IEEE mode an implementation may return 0 instead of a denormalized number, and may return a large number instead of an infinity.
4.3 Floating-Point Data

4.3.1 Data Format

This architecture defines the representation of a floating-point value in two different binary fixed-length formats. The format may be a 32-bit single format for a single-precision value or a 64-bit double format for a double-precision value. The single format may be used for data in storage. The double format may be used for data in storage and for data in floating-point registers.

The lengths of the exponent and the fraction fields differ between these two formats. The structure of the single and double formats is shown below.

<table>
<thead>
<tr>
<th>S</th>
<th>EXP</th>
<th>FRACTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>9</td>
</tr>
</tbody>
</table>

Figure 53. Floating-point single format

<table>
<thead>
<tr>
<th>S</th>
<th>EXP</th>
<th>FRACTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>12</td>
</tr>
</tbody>
</table>

Figure 54. Floating-point double format

Values in floating-point format are composed of three fields:

- **S**: sign bit
- **EXP**: exponent + bias
- **FRACTION**: fraction

Representation of numeric values in the floating-point formats consists of a sign bit (S), a biased exponent (EXP), and the fraction portion (FRACTION) of the significand. The significand consists of a leading implied bit concatenated on the right with the FRACTION. This leading implied bit is 1 for normalized numbers and 0 for denormalized numbers and is located in the unit bit position (i.e., the first bit to the left of the binary point). Values representable within the two floating-point formats can be specified by the parameters listed in Figure 55.

```
<table>
<thead>
<tr>
<th>Format</th>
<th>Single</th>

<td>53</td>
</tr>
</tbody>
</table>
```

Figure 55. IEEE floating-point fields

The architecture requires that the FPRs of the Floating-Point Facility support the floating-point double format only.

4.3.2 Value Representation

This architecture defines numeric and non-numeric values representable within each of the two supported formats. The numeric values are approximations to the real numbers and include the normalized numbers, denormalized numbers, and zero values. The non-numeric values representable are the infinities and the Not a Numbers (NaNs). The infinities are adjoined to the real numbers, but are not numbers themselves, and the standard rules of arithmetic do not hold when they are used in an operation. They are related to the real numbers by order alone. It is possible however to define restricted operations among numbers and infinities as defined below. The relative location on the real number line for each of the defined entities is shown in Figure 56.

```
-Inf -NOR -Den 0 +Den +NOR +Inf
```

Figure 56. Approximation to real numbers

The NaNs are not related to the numeric values or infinities by order or value but are encodings used to convey diagnostic information such as the representation of uninitialized variables.

The following is a description of the different floating-point values defined in the architecture:

**Binary floating-point numbers**

Machine representable values used as approximations to real numbers. Three categories of numbers are supported: normalized numbers, denormalized numbers, and zero values.
Normalized numbers (± NOR)
These are values that have a biased exponent value in the range:

1 to 254 in single format
1 to 2046 in double format

They are values in which the implied unit bit is 1. Normalized numbers are interpreted as follows:

\[ \text{NOR} = (-1)^s \times 2^E \times (1.\text{fraction}) \]

where \( s \) is the sign, \( E \) is the unbiased exponent, and 1.\text{fraction} is the significand, which is composed of a leading unit bit (implied bit) and a fraction part.

The ranges covered by the magnitude \( M \) of a normalized floating-point number are approximately equal to:

Single Format:
\[ 1.2 \times 10^{-38} \leq M \leq 3.4 \times 10^{38} \]

Double Format:
\[ 2.2 \times 10^{-308} \leq M \leq 1.8 \times 10^{308} \]

Zero values (± 0)
These are values that have a biased exponent value of zero and a fraction value of zero. Zeros can have a positive or negative sign. The sign of zero is ignored by comparison operations (i.e., comparison regards +0 as equal to −0).

Denormalized numbers (± DEN)
These are values that have a biased exponent value of zero and a nonzero fraction value. They are nonzero numbers smaller in magnitude than the representable normalized numbers. They are values in which the implied unit bit is 0. Denormalized numbers are interpreted as follows:

\[ \text{DEN} = (-1)^s \times 2^{E_{\text{min}}} \times (0.\text{fraction}) \]

where \( E_{\text{min}} \) is the minimum representable exponent value (−126 for single-precision, −1022 for double-precision).

Infinities (± ∞)
These are values that have the maximum biased exponent value:

255 in single format
2047 in double format

and a zero fraction value. They are used to approximate values greater in magnitude than the maximum normalized value.

Infinity arithmetic is defined as the limiting case of real arithmetic, with restricted operations defined among numbers and infinities. Infinities and the real numbers can be related by ordering in the affine sense:

\[-\infty < \text{every finite number} < +\infty\]

Arithmetic on infinities is always exact and does not signal any exception, except when an exception occurs due to the invalid operations as described in Section 4.4.1, "Invalid Operation Exception" on page 126.

For comparison operations, +Infinity compares equal to +Infinity and -Infinity compares equal to -Infinity.

Not a Numbers (NaNs)
These are values that have the maximum biased exponent value and a nonzero fraction value. The sign bit is ignored (i.e., NaNs are neither positive nor negative). If the high-order bit of the fraction field is 0 then the NaN is a Signaling NaN; otherwise it is a Quiet NaN.

Signaling NaNs are used to signal exceptions when they appear as operands of computational instructions. Quiet NaNs are used to represent the results of certain invalid operations, such as invalid arithmetic operations on infinities or on NaNs, when Invalid Operation Exception is disabled (FPSCR.VE=0). Quiet NaNs propagate through all floating-point operations except ordered comparison, Floating Round to Single-Precision, and conversion to integer. Quiet NaNs do not signal exceptions, except for ordered comparison and conversion to integer operations. Specific encodings in QNaNs can thus be preserved through a sequence of floating-point operations, and used to convey diagnostic information to help identify results from invalid operations.

When a QNaN is the result of a floating-point operation because one of the operands is a NaN or because a QNaN was generated due to a disabled Invalid Operation Exception, then the following rule is applied to determine the NaN with the high-order fraction bit set to 1 that is to be stored as the result.

\[
\text{if (FRA) is a NaN then } FRT \leftarrow \text{(FRA)} \\
\text{else if (FRB) is a NaN then } FRT \leftarrow \text{(FRB)} \\
\text{else if generated QNaN then } FRT \leftarrow \text{generated QNaN}
\]

If the operand specified by FRA is a NaN, then that NaN is stored as the result. Otherwise, if the operand specified by FRB is a NaN (if the instruction specifies an FRB operand), then that NaN is stored as the result, with the low-order 29 bits of the result set to 0 if the instruction is \text{frsp}. Otherwise, if the operand specified by FRC is a NaN (if the instruction specifies an FRC operand), then that NaN is stored as the result. Otherwise, if a QNaN was generated due to a disabled Invalid Operation Exception, then that QNaN is stored as the result. If a QNaN is to be generated as a result, then the QNaN generated has a sign bit of 0, an exponent field of all 1s, and a high-order fraction bit of 1 with all other fraction bits 0. Any instruction that generates a QNaN as the result of a disabled Invalid Operation Exception.
A double-precision NaN is considered to be representable in single format if and only if the low-order 29 bits of the double-precision NaN’s fraction are zero.

**4.3.3 Sign of Result**

The following rules govern the sign of the result of an arithmetic, rounding, or conversion operation, when the operation does not yield an exception. They apply even when the operands or results are zeros or infinities.

- The sign of the result of an add operation is the sign of the operand having the larger absolute value. If both operands have the same sign, the sign of the result of an add operation is the same as the sign of the operands. The sign of the result of the subtract operation \(x - y\) is the same as the sign of the result of the add operation \(x + (-y)\).

- When the sum of two operands with opposite sign, or the difference of two operands with the same sign, is exactly zero, the sign of the result is positive in all rounding modes except Round toward \(-\infty\), in which mode the sign is negative.

- The sign of the result of a multiply or divide operation is the Exclusive OR of the signs of the operands.

- The sign of the result of a Square Root or Reciprocal Square Root Estimate operation is always positive, except that the square root of \(-0\) is \(-0\) and the reciprocal square root of \(-0\) is \(-\infty\).

- The sign of the result of a Round to Single-Precision, or Convert From Integer, or Round to Integer operation is the sign of the operand being converted.

For the Multiply-Add instructions, the rules given above are applied first to the multiply operation and then to the add or subtract operation (one of the inputs to the add or subtract operation is the result of the multiply operation).

**4.3.4 Normalization and Denormalization**

The intermediate result of an arithmetic or \texttt{frsp} instruction may require normalization and/or denormalization as described below. Normalization and denormalization do not affect the sign of the result.

When an arithmetic or rounding instruction produces an intermediate result which carries out of the significand, or in which the significand is nonzero but has a leading zero bit, it is not a normalized number and must be normalized before it is stored. For the carry-out case, the significand is shifted right one bit, with a one shifted into the leading significand bit, and the exponent is incremented by one. For the leading-zero case, the significand is shifted left while decrementing its exponent by one for each bit shifted, until the leading significand bit becomes one. The Guard bit and the Round bit (see Section 4.5.1, “Execution Model for IEEE Operations” on page 129) participate in the shift with zeros shifted into the Round bit. The exponent is regarded as if its range were unlimited.

After normalization, or if normalization was not required, the intermediate result may have a nonzero significand and an exponent value that is less than the minimum value that can be represented in the format specified for the result. In this case, the intermediate result is said to be “Tiny” and the stored result is determined by the rules described in Section 4.4.4, “Underflow Exception”. These rules may require denormalization.

A number is denormalized by shifting its significand right while incrementing its exponent by 1 for each bit shifted, until the exponent is equal to the format’s minimum value. If any significant bits are lost in this shifting process then “Loss of Accuracy” has occurred (See Section 4.4.4, “Underflow Exception” on page 128) and Underflow Exception is signaled.

**4.3.5 Data Handling and Precision**

Most of the Floating-Point Facility Architecture, including all computational, Move, and Select instructions, use the floating-point double format to represent data in the FPRs. Single-precision and integer-valued operands may be manipulated using double-precision operations. Instructions are provided to coerce these values from a double format operand. Instructions are also provided for manipulations which do not require double-precision. In addition, instructions are provided to access a true single-precision representation in storage, and a fixed-point integer representation in GPRs.

**4.3.5.1 Single-Precision Operands**

For single format data, a format conversion from single to double is performed when loading from storage into an FPR and a format conversion from double to single is performed when storing from an FPR to storage. No floating-point exceptions are caused by these instructions. An instruction is provided to explicitly convert a double format operand in an FPR to single-precision. Floating-point single-precision is enabled with four types of instruction.

1. Load Floating-Point Single

This form of instruction accesses a single-precision operand in single format in storage, converts it to double format, and loads it into an FPR. No floating-point exceptions are caused by these instructions.
2. Round to Floating-Point Single-Precision

The Floating Round to Single-Precision instruction rounds a double-precision operand to single-precision, checking the exponent for single-precision range and handling any exceptions according to respective enable bits, and places that operand into an FPR in double format. For results produced by single-precision arithmetic instructions, single-precision loads, and other instances of the Floating Round to Single-Precision instruction, this operation does not alter the value.

3. Single-Precision Arithmetic Instructions

This form of instruction takes operands from the FPRs in double format, performs the operation as if it produced an intermediate result having infinite precision and unbounded exponent range, and then coerces this intermediate result to fit in single format. Status bits, in the FPSCR and optionally in the Condition Register, are set to reflect the single-precision result. The result is then converted to double format and placed into an FPR. The result lies in the range supported by the single format.

If any input value is not representable in single format and either OE=1 or UE=1, the result placed into the target FPR, and the setting of status bits in the FPSCR and in the Condition Register (if Rc=1), are undefined.

For fres[,.] or frsqrtes[,], if the input value is finite and has an unbiased exponent greater than +127, the input value is interpreted as an Infinity.

4. Store Floating-Point Single

This form of instruction converts a double-precision operand to single format and stores that operand into storage. No floating-point exceptions are caused by these instructions. (The value being stored is effectively assumed to be the result of an instruction of one of the preceding three types.)

When the result of a Load Floating-Point Single, Floating Round to Single-Precision, or single-precision arithmetic instruction is stored in an FPR, the low-order 29 FRACTION bits are zero.

Programming Note

The Floating Round to Single-Precision instruction is provided to allow value conversion from double-precision to single-precision with appropriate exception checking and rounding. This instruction should be used to convert double-precision floating-point values (produced by double-precision load and arithmetic instructions and by fcfid) to single-precision values prior to storing them into single format storage elements or using them as operands for single-precision arithmetic instructions. Values produced by single-precision load and arithmetic instructions are already single-precision values and can be stored directly into single format storage elements, or used directly as operands for single-precision arithmetic instructions, without preceding the store, or the arithmetic instruction, by a Floating Round to Single-Precision instruction.

Programming Note

A single-precision value can be used in double-precision arithmetic operations. The reverse is true only if the double-precision value is representable in single format.

Some implementations may execute single-precision arithmetic instructions faster than double-precision arithmetic instructions. Therefore, if double-precision accuracy is not required, single-precision data and instructions should be used.

4.3.5.2 Integer-Valued Operands

Instructions are provided to round floating-point operands to integer values in floating-point format. To facilitate exchange of data between the floating-point and fixed-Point facilities, instructions are provided to convert between floating-point double format and fixed-point integer format in an FPR. Computation on integer-valued operands may be performed using arithmetic instructions of the required precision. (The results may not be integer values.) The two groups of instructions provided specifically to support integer-valued operands are described below.

1. Floating Round to Integer

The Floating Round to Integer instructions round a double-precision operand to an integer value in floating-point double format. These instructions may cause Invalid Operation (VXSNAN) exceptions. See Sections 4.3.6 and 4.5.1 for more information about rounding.

2. Floating Convert To/From Integer

The Floating Convert To/Integer instructions convert a double-precision operand to a 32-bit or 64-bit signed fixed-point integer format. Variants are provided both to perform rounding based on
the value of FPSCR\textsubscript{RN} and to round toward zero. These instructions may cause Invalid Operation (VXSNaN, VXCVI) and Inexact exceptions. The
Floating Convert From Integer instruction converts a 64-bit signed fixed-point integer to a double-precision floating-point integer. Because of the limitations of the source format, only an Inexact exception may be generated.

### 4.3.6 Rounding

The material in this section applies to operations that have numeric operands (i.e., operands that are not infinities or NaNs). Rounding the intermediate result of such an operation may cause an Overflow Exception, an Underflow Exception, or an Inexact Exception. The remainder of this section assumes that the operation causes no exceptions and that the result is numeric. See Section 4.3.2, “Value Representation” and Section 4.4, “Floating-Point Exceptions” for the cases not covered here.

The Arithmetic and Rounding and Conversion instructions round their intermediate results. With the exception of the Estimate instructions, these instructions produce an intermediate result that can be regarded as having infinite precision and unbounded exponent range. All but two groups of these instructions normalize or denormalize the intermediate result prior to rounding and then place the final result into the target FPR in double format. The Floating Round to Integer and Floating Convert To Integer instructions with biased exponents ranging from 1022 through 1074 are prepared for rounding by repetitively shifting the significand right one position and incrementing the biased exponent until it reaches a value of 1075. (Intermediate results with biased exponents 1075 or larger are already integers, and with biased exponents 1021 or less round to zero.) After rounding, the final result for Floating Round to Integer is normalized and put in double format, and for Floating Convert To Integer is converted to a signed fixed-point integer.

FPSCR bits FR and FI generally indicate the results of rounding. Each of the instructions which rounds its intermediate result sets these bits. If the fraction is incremented during rounding then FR is set to 1, otherwise FR is set to 0. If the result is inexact then FI is set to 1, otherwise FI is set to zero. The Round to Integer instructions are exceptions to this rule, setting FR and FI to 0. The Estimate instructions set FR and FI to undefined values. The remaining floating-point instructions do not alter FR and FI.

Four user-selectable rounding modes are provided through the Floating-Point Rounding Control field in the FPSCR. See Section 4.2.2, “Floating-Point Status and Control Register”. These are encoded as follows.

<table>
<thead>
<tr>
<th>RN</th>
<th>Rounding Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Round to Nearest</td>
</tr>
<tr>
<td>01</td>
<td>Round toward Zero</td>
</tr>
<tr>
<td>10</td>
<td>Round toward +Infinity</td>
</tr>
<tr>
<td>11</td>
<td>Round toward -Infinity</td>
</tr>
</tbody>
</table>

Let Z be the intermediate arithmetic result or the operand of a convert operation. If Z can be represented exactly in the target format, then the result in all rounding modes is Z as represented in the target format. If Z cannot be represented exactly in the target format, let Z1 and Z2 bound Z as the next larger and next smaller numbers representable in the target format. Then Z1 or Z2 can be used to approximate the result in the target format.

Figure 57 shows the relation of Z, Z1, and Z2 in this case. The following rules specify the rounding in the four modes. “LSB” means “least significant bit”.

#### Figure 57. Selection of Z1 and Z2

**Round to Nearest**

Choose the value that is closer to Z (Z1 or Z2).

In case of a tie, choose the one that is even (least significant bit 0).

**Round toward Zero**

Choose the smaller in magnitude (Z1 or Z2).

**Round toward +Infinity**

Choose Z1.

**Round toward -Infinity**

Choose Z2.

See Section 4.5.1, “Execution Model for IEEE Operations” on page 129 for a detailed explanation of rounding.
4.4 Floating-Point Exceptions

This architecture defines the following floating-point exceptions:

- Invalid Operation Exception
  - SNaN
  - Infinity-Infinity
  - Infinity-Infinity
  - Zero/Zero
  - Infinity-Zero
  - Invalid Compare
  - Software-Defined Condition
  - Invalid Square Root
  - Invalid Integer Convert
- Zero Divide Exception
- Overflow Exception
- Underflow Exception
- Inexact Exception

These exceptions, other than Invalid Operation Exception due to Software-Defined Condition, may occur during execution of computational instructions. An Invalid Operation Exception due to Software-Defined Condition occurs when a Move To FPSCR instruction sets FPSCR\_VXSOFT to 1.

Each floating-point exception, and each category of Invalid Operation Exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. The exception bit indicates occurrence of the corresponding exception. If an exception occurs, the corresponding enable bit governs the result produced by the instruction and, in conjunction with the FE0 and FE1 bits (see page 125), whether and how the system floating-point enabled exception error handler is invoked. (In general, the enabling specified by the enable bit is of invoking the system error handler, not of permitting the exception to occur. The occurrence of an exception depends only on the instruction and its inputs, not on the setting of any control bits. The only deviation from this general rule is that the occurrence of an Underflow Exception may depend on the setting of the enable bit.)

A single instruction, other than mtfsi or mtfs, may set more than one exception bit only in the following cases:

- Inexact Exception may be set with Overflow Exception.
- Inexact Exception may be set with Underflow Exception.
- Invalid Operation Exception (SNaN) is set with Invalid Operation Exception (\(<\times0\)) for Multiply-Add instructions for which the values being multiplied are infinity and zero and the value being added is an SNaN.
- Invalid Operation Exception (SNaN) may be set with Invalid Operation Exception (Invalid Compare) for Compare Ordered instructions.
- Invalid Operation Exception (SNaN) may be set with Invalid Operation Exception (Invalid Integer Convert) for Convert To Integer instructions.

When an exception occurs the writing of a result to the target register may be suppressed or a result may be delivered, depending on the exception.

The writing of a result to the target register is suppressed for the following kinds of exception, so that there is no possibility that one of the operands is lost:

- Enabled Invalid Operation
- Enabled Zero Divide

For the remaining kinds of exception, a result is generated and written to the destination specified by the instruction causing the exception. The result may be a different value for the enabled and disabled conditions for some of these exceptions. The kinds of exception that deliver a result are the following:

- Disabled Invalid Operation
- Disabled Zero Divide
- Disabled Overflow
- Disabled Underflow
- Disabled Inexact
- Enabled Overflow
- Enabled Underflow
- Enabled Inexact

Subsequent sections define each of the floating-point exceptions and specify the action that is taken when they are detected.

The IEEE standard specifies the handling of exceptional conditions in terms of "traps" and "trap handlers". In this architecture, an FPSCR exception enable bit of 1 causes generation of the result value specified in the IEEE standard for the "trap enabled" case; the expectation is that the exception will be detected by software, which will revise the result. An FPSCR exception enable bit of 0 causes generation of the "default result" value specified for the "trap disabled" (or "no trap occurs" or "trap is not implemented") case; the expectation is that the exception will not be detected by software, which will simply use the default result. The result to be delivered in each case for each exception is described in the sections below.

The IEEE default behavior when an exception occurs is to generate a default value and not to notify software. In this architecture, if the IEEE default behavior when an exception occurs is desired for all exceptions, all FPSCR exception enable bits should be set to 0 and Ignore Exceptions Mode (see below) should be used. In this case the system floating-point enabled exception error handler is not invoked, even if floating-point exceptions occur: software can inspect the FPSCR exception bits if necessary, to determine whether exceptions have occurred.

In this architecture, if software is to be notified that a given kind of exception has occurred, the corresponding FPSCR exception enable bit must be set to 1 and a mode other than Ignore Exceptions Mode must be used. In this case the system floating-point enabled exception error handler is invoked if an enabled float-
ing-point exception occurs. The system floating-point enabled exception error handler is also invoked if a Move To FPSCR instruction causes an exception bit and the corresponding enable bit both to be 1; the Move To FPSCR instruction is considered to cause the enabled exception.

The FE0 and FE1 bits control whether and how the system floating-point enabled exception error handler is invoked if an enabled floating-point exception occurs. The location of these bits and the requirements for altering them are described in Book III. (The system floating-point enabled exception error handler is never invoked because of a disabled floating-point exception.) The effects of the four possible settings of these bits are as follows.

**FE0 FE1 Description**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>Description</th>
</tr>
</thead>
</table>
| 0 | 0 | Ignore Exceptions Mode  
Floating-point exceptions do not cause the system floating-point enabled exception error handler to be invoked. |
| 0 | 1 | Imprecise Nonrecoverable Mode  
The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. It may not be possible to identify the excepting instruction or the data that caused the exception. Results produced by the excepting instruction may have been used by or may have affected subsequent instructions that are executed before the error handler is invoked. |
| 1 | 0 | Imprecise Recoverable Mode  
The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. Sufficient information is provided to the error handler that it can identify the excepting instruction and the operands, and correct the result. No results produced by the excepting instruction have been affected by or have affected subsequent instructions that are executed before the error handler is invoked. |
| 1 | 1 | Precise Mode  
The system floating-point enabled exception error handler is invoked precisely at the instruction that caused the enabled exception. |

In all cases, the question of whether a floating-point result is stored, and what value is stored, is governed by the FPSCR exception enable bits, as described in subsequent sections, and is not affected by the value of the FE0 and FE1 bits.

In all cases in which the system floating-point enabled exception error handler is invoked, all instructions before the instruction at which the system floating-point enabled exception error handler is invoked have completed, and no instruction after the instruction at which the system floating-point enabled exception error handler is invoked has begun execution. The instruction at which the system floating-point enabled exception error handler is invoked has completed if it is the excepting instruction and there is only one such instruction. Otherwise it has not begun execution (or may have been partially executed in some cases, as described in Book III).

**Programming Note**

In any of the three non-Precise modes, a Floating-Point Status and Control Register instruction can be used to force any exceptions, due to instructions initiated before the Floating-Point Status and Control Register instruction, to be recorded in the FPSCR. (This forcing is superfluous for Precise Mode.)

In either of the Imprecise modes, a Floating-Point Status and Control Register instruction can be used to force any invocations of the system floating-point enabled exception error handler, due to instructions initiated before the Floating-Point Status and Control Register instruction, to occur. (This forcing has no effect in Ignore Exceptions Mode, and is superfluous for Precise Mode.)

The last sentence of the paragraph preceding this Programming Note can apply only in the Imprecise modes, or if the mode has just been changed from Ignore Exceptions Mode to some other mode. (It always applies in the latter case.)

In order to obtain the best performance across the widest range of implementations, the programmer should obey the following guidelines.

- If the IEEE default results are acceptable to the application, Ignore Exceptions Mode should be used with all FPSCR exception enable bits set to 0.
- If the IEEE default results are not acceptable to the application, Imprecise Nonrecoverable Mode should be used, or Imprecise Recoverable Mode if recoverability is needed, with FPSCR exception enable bits set to 1 for those exceptions for which the system floating-point enabled exception error handler is to be invoked.
- Ignore Exceptions Mode should not, in general, be used when any FPSCR exception enable bits are set to 1.
- Precise Mode may degrade performance in some implementations, perhaps substantially, and therefore should be used only for debugging and other specialized applications.
4.4.1 Invalid Operation Exception

4.4.1.1 Definition

An Invalid Operation Exception occurs when an operand is invalid for the specified operation. The invalid operations are:

- Any floating-point operation on a Signaling NaN (SNaN)
- For add or subtract operations, magnitude subtraction of infinities (\(\infty - \infty\))
- Division of infinity by infinity (\(\infty / \infty\))
- Division of zero by zero (0 ÷ 0)
- Multiplication of infinity by zero (\(\infty \times 0\))
- Ordered comparison involving a NaN (Invalid Compare)
- Square root or reciprocal square root of a negative (and nonzero) number (Invalid Square Root)
- Integer convert involving a number too large in magnitude to be represented in the target format, or involving an infinity or a NaN (Invalid Integer Convert)

An Invalid Operation Exception also occurs when an \(\text{mtfsfi}\), \(\text{mtsf}\), or \(\text{mtfsb1}\) instruction is executed that sets FPSCR\(_{VXSOFT}\) to 1 (Software-Defined Condition).

4.4.1.2 Action

The action to be taken depends on the setting of the Invalid Operation Exception Enable bit of the FPSCR.

When Invalid Operation Exception is enabled (FPSCR\(_{VE}\)=1) and an Invalid Operation Exception occurs, the following actions are taken:

1. One or two Invalid Operation Exceptions are set
   - FPSCR\(_{VXS}\) (if SNaN)
   - FPSCR\(_{VX}\) (if \(\infty - \infty\))
   - FPSCR\(_{VX}\) (if \(\infty / \infty\))
   - FPSCR\(_{VX}\) (if 0 ÷ 0)
   - FPSCR\(_{VX}\) (if invalid comp)
   - FPSCR\(_{VXS}\) (if invalid sqrt)
   - FPSCR\(_{VX}\) (if invalid int cvrt)

2. If the operation is an arithmetic, Floating Round to Single-Precision operation, the target FPR is set to a Quiet NaN
   - FPSCR\(_{FRF}\) are set to zero
   - FPSCR\(_{FFP}\) is set to indicate the class of the result (Quiet NaN)

3. If the operation is a convert to 64-bit integer operation, the target FPR is set as follows:
   - FPSCR\(_{FRF}\) are set to zero
   - FPSCR\(_{FFP}\) is undefined

4. If the operation is a compare, FPSCR\(_{FRF}\) are unchanged
   - FPSCR\(_{FFP}\) is set to reflect unordered

5. If an \(\text{mtfsfi}\), \(\text{mtsf}\), or \(\text{mtfsb1}\) instruction is executed that sets FPSCR\(_{VXS}\) to 1, the FPSCR is set as specified in the instruction description.

When Invalid Operation Exception is disabled (FPSCR\(_{VE}\)=0) and an Invalid Operation Exception occurs, the following actions are taken:

1. One or two Invalid Operation Exceptions are set
   - FPSCR\(_{VXS}\) (if SNaN)
   - FPSCR\(_{VX}\) (if \(\infty - \infty\))
   - FPSCR\(_{VX}\) (if \(\infty / \infty\))
   - FPSCR\(_{VX}\) (if 0 ÷ 0)
   - FPSCR\(_{VX}\) (if invalid comp)
   - FPSCR\(_{VXS}\) (if invalid sqrt)
   - FPSCR\(_{VX}\) (if invalid int cvrt)

2. If the operation is an arithmetic or Floating Round to Single-Precision operation, the target FPR is set to a Quiet NaN
   - FPSCR\(_{FRF}\) are set to zero
   - FPSCR\(_{FFP}\) is set to indicate the class of the result (Quiet NaN)

4. If the operation is a convert to 32-bit integer operation, the target FPR is set as follows:
   - FPSCR\(_{FRF}\) are set to zero
   - FPSCR\(_{FFP}\) is undefined

5. If the operation is a compare, FPSCR\(_{FRF}\) are unchanged
   - FPSCR\(_{FFP}\) is set to reflect unordered

6. If an \(\text{mtfsfi}\), \(\text{mtsf}\), or \(\text{mtfsb1}\) instruction is executed that sets FPSCR\(_{VXS}\) to 1, the FPSCR is set as specified in the instruction description.

4.4.2 Zero Divide Exception

4.4.2.1 Definition

A Zero Divide Exception occurs when a Divide instruction is executed with a zero divisor value and a finite nonzero dividend value. It also occurs when a Reciprocal Estimate instruction \((\text{fr[s]}\) or \(\text{frsqrte[s]}\)) is executed with an operand value of zero.

4.4.2.2 Action

The action to be taken depends on the setting of the Zero Divide Exception Enable bit of the FPSCR.

When Zero Divide Exception is enabled (FPSCRZE=1) and a Zero Divide Exception occurs, the following actions are taken:

1. Zero Divide Exception is set
   FPSCRZX ← 1
2. The target FPR is unchanged
3. FPSCRFR FI are set to zero
4. FPSCRFPRF is unchanged

When Zero Divide Exception is disabled (FPSCRZE=0) and a Zero Divide Exception occurs, the following actions are taken:

1. Zero Divide Exception is set
   FPSCRZX ← 1
2. The target FPR is set to ±Infinity, where the sign is determined by the XOR of the signs of the operands
3. FPSCRFR FI are set to zero
4. FPSCRFPRF is set to indicate the class and sign of the result (±Infinity)

4.4.3 Overflow Exception

4.4.3.1 Definition

An Overflow Exception occurs when the magnitude of what would have been the rounded result if the exponent range were unbounded exceeds that of the largest finite number of the specified result precision.

4.4.3.2 Action

The action to be taken depends on the setting of the Overflow Exception Enable bit of the FPSCR.

When Overflow Exception is enabled (FPSCROE=1) and an Overflow Exception occurs, the following actions are taken:

1. Overflow Exception is set
   FPSCRXX ← 1
2. For double-precision arithmetic instructions, the exponent of the normalized intermediate result is adjusted by subtracting 1536
3. For single-precision arithmetic instructions and the Floating Round to Single-Precision instruction, the exponent of the normalized intermediate result is adjusted by subtracting 192
4. The adjusted rounded result is placed into the target FPR
5. FPSCRFPRF is set to indicate the class and sign of the result (±Infinity or ±Normal Number)

1. Overflow Exception is set
   FPSCRXX ← 1
2. Inexact Exception is set
   FPSCRXX ← 1
3. The result is determined by the rounding mode (FPSCRRN) and the sign of the intermediate result as follows:
   - Round to Nearest
     Store ±Infinity, where the sign is the sign of the intermediate result
   - Round toward Zero
     Store the format’s largest finite number with the sign of the intermediate result
   - Round toward +Infinity
     For negative overflow, store the format’s most negative finite number; for positive overflow, store +Infinity
   - Round toward −Infinity
     For negative overflow, store −Infinity; for positive overflow, store the format’s largest finite number
4. The result is placed into the target FPR
5. FPSCRF is undefined
6. FPSCRFI is set to 1
7. FPSCRFPRF is set to indicate the class and sign of the result (±Infinity or ±Normal Number)
4.4.4 Underflow Exception

4.4.4.1 Definition

Underflow Exception is defined separately for the enabled and disabled states:

- **Enabled:**
  Underflow occurs when the intermediate result is “Tiny”.

- **Disabled:**
  Underflow occurs when the intermediate result is “Tiny” and there is “Loss of Accuracy”.

A “Tiny” result is detected before rounding, when a non-zero intermediate result computed as though both the precision and the exponent range were unbounded would be less in magnitude than the smallest normalized number.

If the intermediate result is “Tiny” and Underflow Exception is disabled (FPSCR\_UE=0) then the intermediate result is denormalized (see Section 4.3.4, “Normalization and Denormalization” on page 121) and rounded (see Section 4.3.6, “Rounding” on page 123) before being placed into the target FPR.

“Loss of Accuracy” is detected when the delivered result value differs from what would have been computed were both the precision and the exponent range unbounded.

4.4.4.2 Action

The action to be taken depends on the setting of the Underflow Exception Enable bit of the FPSCR.

When Underflow Exception is enabled (FPSCR\_UE=1) and an Underflow Exception occurs, the following actions are taken:

1. Underflow Exception is set
   \[ FPSCR\_UX \leftarrow 1 \]

2. For double-precision arithmetic instructions, the exponent of the normalized intermediate result is adjusted by adding 1536

3. For single-precision arithmetic instructions and the Floating Round to Single-Precision instruction, the exponent of the normalized intermediate result is adjusted by adding 192

4. The adjusted rounded result is placed into the target FPR

5. FPSCR\_FPREF is set to indicate the class and sign of the result (± Normalized Number)

When Underflow Exception is disabled (FPSCR\_UE=0) and an Underflow Exception occurs, the following actions are taken:

1. Underflow Exception is set
   \[ FPSCR\_UX \leftarrow 1 \]

2. The rounded result is placed into the target FPR

3. FPSCR\_FPREF is set to indicate the class and sign of the result (± Normalized Number, ± Denormalized Number, or ± Zero)

4.4.5 Inexact Exception

4.4.5.1 Definition

An Inexact Exception occurs when one of two conditions occur during rounding:

1. The rounded result differs from the intermediate result assuming both the precision and the exponent range of the intermediate result to be unbounded. In this case the result is said to be inexact. (If the rounding causes an enabled Overflow Exception or an enabled Underflow Exception, an Inexact Exception also occurs only if the significands of the rounded result and the intermediate result differ.)

2. The rounded result overflows and Overflow Exception is disabled.

4.4.5.2 Action

The action to be taken does not depend on the setting of the Inexact Exception Enable bit of the FPSCR.

When an Inexact Exception occurs, the following actions are taken:

1. Inexact Exception is set
   \[ FPSCR\_XX \leftarrow 1 \]

2. The rounded or overflowed result is placed into the target FPR

3. FPSCR\_FPREF is set to indicate the class and sign of the result

---

**Programming Note**

The FR and FI bits are provided to allow the system floating-point enabled exception error handler, when invoked because of an Underflow Exception, to simulate a “trap disabled” environment. That is, the FR and FI bits allow the system floating-point enabled exception error handler to unround the result, thus allowing the result to be denormalized.

When Underflow Exception is disabled (FPSCR\_UE=0) and an Underflow Exception occurs, the following actions are taken:

1. Underflow Exception is set
   \[ FPSCR\_UX \leftarrow 1 \]

2. The rounded result is placed into the target FPR

3. FPSCR\_FPREF is set to indicate the class and sign of the result (± Normalized Number, ± Denormalized Number, or ± Zero)

---

**Programming Note**

In some implementations, enabling Inexact Exceptions may degrade performance more than does enabling other types of floating-point exception.
4.5 Floating-Point Execution Models

All implementations of this architecture must provide the equivalent of the following execution models to ensure that identical results are obtained.

Special rules are provided in the definition of the computational instructions for the infinities, denormalized numbers and NaNs. The material in the remainder of this section applies to instructions that have numeric operands and a numeric result (i.e., operands and result that are not infinities or NaNs), and that cause no exceptions. See Section 4.3 and Section 4.4 for the cases not covered here.

Although the double format specifies an 11-bit exponent, exponent arithmetic makes use of two additional bits to avoid potential transient overflow conditions. One extra bit is required when denormalized double-precision numbers are prenormalized. The second bit is required to permit the computation of the adjusted exponent value in the following cases when the corresponding exception enable bit is 1:

- Underflow during multiplication using a denormalized operand.
- Overflow during division using a denormalized divisor.

The IEEE standard includes 32-bit and 64-bit arithmetic. The standard requires that single-precision arithmetic be provided for single-precision operands. The standard permits double-precision floating-point operations to have either (or both) single-precision or double-precision operands, but states that single-precision floating-point operations should not accept double-precision operands. The Power ISA follows these guidelines; double-precision arithmetic instructions can have operands of either or both precisions, while single-precision arithmetic instructions require all operands to be single-precision. Double-precision arithmetic instructions and `fcf` produce double-precision values, while single-precision arithmetic instructions produce single-precision values.

For arithmetic instructions, conversions from double-precision to single-precision must be done explicitly by software, while conversions from single-precision to double-precision are done implicitly.

4.5.1 Execution Model for IEEE Operations

The following description uses 64-bit arithmetic as an example. 32-bit arithmetic is similar except that the FRACTION is a 23-bit field, and the single-precision Guard, Round, and Sticky bits (described in this section) are logically adjacent to the 23-bit FRACTION field.

IEEE-conforming significand arithmetic is considered to be performed with a floating-point accumulator having the following format, where bits 0:55 comprise the significand of the intermediate result.

<table>
<thead>
<tr>
<th>S</th>
<th>C</th>
<th>L</th>
<th>FRACTION</th>
<th>G</th>
<th>R</th>
<th>X</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>53</td>
<td>54</td>
<td>55</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Figure 58. IEEE 64-bit execution model

The S bit is the sign bit.

The C bit is the carry bit, which captures the carry out of the significand.

The L bit is the leading unit bit of the significand, which receives the implicit bit from the operand.

The FRACTION is a 52-bit field that accepts the fraction of the operand.

The Guard (G), Round (R), and Sticky (X) bits are extensions to the low-order bits of the accumulator. The G and R bits are required for postnormalization of the result. The G, R, and X bits are required during rounding to determine if the intermediate result is equally near the two nearest representable values. The X bit serves as an extension to the G and R bits by representing the logical OR of all bits that may appear to the low-order side of the R bit, due to shifting the accumulator right or to other generation of low-order result bits. The G and R bits participate in the shifts with zeros being shifted into the R bit. Figure 59 shows the significance of the G, R, and X bits with respect to the intermediate result (IR), the representable number next lower in magnitude (NL), and the representable number next higher in magnitude (NH).

<table>

</thead>
<tbody>
<tr>
<td>Double</td>
<td>G bit</td>
<td>R bit</td>
<td>X bit</td>
</tr>
</tbody>
</table>

Figure 60. Location of the Guard, Round, and Sticky bits in the IEEE execution model
The significand of the intermediate result is prepared for rounding by shifting its contents right, if required, until the least significant bit to be retained is in the low-order bit position of the fraction. Four user-selectable rounding modes are provided through FPSCR_RN as described in Section 4.3.6, “Rounding” on page 123. Using Z1 and Z2 as defined on page 123, the rules for rounding in each mode are as follows.

- **Round to Nearest**
  - **Guard bit = 0**
    The result is truncated. (Result exact (GRX=000) or closest to next lower value in magnitude (GRX=001, 010, or 011))
  - **Guard bit = 1**
    Depends on Round and Sticky bits:
    - **Case a**
      If the Round or Sticky bit is 1 (inclusive), the result is incremented. (Result closest to next higher value in magnitude (GRX=101, 110, or 111))
    - **Case b**
      If the Round and Sticky bits are 0 (result midway between closest representable values), then if the low-order bit of the result is 1 the result is incremented. Otherwise (the low-order bit of the result is 0) the result is truncated (this is the case of a tie rounded to even).

- **Round toward Zero**
  Choose the smaller in magnitude of Z1 or Z2. If the Guard, Round, or Sticky bit is nonzero, the result is inexact.

- **Round toward + Infinity**
  Choose Z1.

- **Round toward - Infinity**
  Choose Z2.

If rounding results in a carry into C, the significand is shifted right one position and the exponent is incremented by one. This yields an inexact result, and possibly also exponent overflow. If any of the Guard, Round, or Sticky bits is nonzero, then the result is also inexact. Fraction bits are stored to the target FPR. For Floating Round to Integer, Floating Round to Single-Precision, and single-precision arithmetic instructions, low-order zeros must be appended as appropriate to fill out the double-precision fraction.
4.5.2 Execution Model for Multiply-Add Type Instructions

The Power ISA provides a special form of instruction that performs up to three operations in one instruction (a multiplication, an addition, and a negation). With this added capability comes the special ability to produce a more exact intermediate result as input to the rounder. 32-bit arithmetic is similar except that the FRACTION field is smaller.

Multiply-add significand arithmetic is considered to be performed with a floating-point accumulator having the following format, where bits 0:106 comprise the significand of the intermediate result.

![Figure 61. Multiply-add 64-bit execution model](image)

The first part of the operation is a multiplication. The multiplication has two 53-bit significands as inputs, which are assumed to be prenormalized, and produces a result conforming to the above model. If there is a carry out of the significand (into the C bit), then the significand is shifted right one position, shifting the L bit (leading unit bit) into the most significant bit of the FRACTION and shifting the C bit (carry out) into the L bit. All 106 bits (L bit, the FRACTION) of the product take part in the add operation. If the exponents of the two inputs to the adder are not equal, the significand of the operand with the smaller exponent is aligned (shifted) to the right by an amount that is added to that exponent to make it equal to the other input's exponent. Zeros are shifted into the left of the significand as it is aligned and bits shifted out of bit 105 of the significand are ORed into the X' bit. The add operation also produces a result conforming to the above model with the X' bit taking part in the add operation.

The result of the addition is then normalized, with all bits of the addition result, except the X' bit, participating in the shift. The normalized result serves as the intermediate result that is input to the rounder.

For rounding, the conceptual Guard, Round, and Sticky bits are defined in terms of accumulator bits. Figure 62 shows the positions of the Guard, Round, and Sticky bits for double-precision and single-precision floating-point numbers in the multiply-add execution model.

![Figure 62. Location of the Guard, Round, and Sticky bits in the multiply-add execution model](image)

The rules for rounding the intermediate result are the same as those given in Section 4.5.1.
4.6 Floating-Point Facility Instructions

For each instruction in this section that defines the use of an Rc bit, the behavior defined for the instruction corresponding to Rc=1 is considered part of the Floating-Point.Record category.
4.6.1 Floating-Point Storage Access Instructions

The Storage Access instructions compute the effective address (EA) of the storage to be accessed as described in Section 1.10.3, “Effective Address Calculation” on page 26.

Programming Note

The ia extended mnemonic permits computing an effective address as a Load or Store instruction would, but loads the address itself into a GPR rather than loading the value that is in storage at that address. This extended mnemonic is described in Section E.10, “Miscellaneous Mnemonics” on page 719.

4.6.1.1 Storage Access Exceptions

Storage accesses will cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (Store only), or if the program attempts to access storage that is unavailable.

4.6.2 Floating-Point Load Instructions

There are three basic forms of load instruction: single-precision, double-precision, and integer. The integer form is provided by the Load Floating-Point as Integer Word Algebraic instruction, described on page 136. Because the FPRs support only floating-point double format, single-precision Load Floating-Point instructions convert single-precision data to double format prior to loading the operand into the target FPR. The conversion and loading steps are as follows.

Let WORD0:31 be the floating-point single-precision operand accessed from storage.

Normalized Operand

if WORD1:8 > 0 and WORD1:8 < 255 then
  FRT0 ← WORD0:1
  FRT2 ← -WORD1
  FRT3 ← -WORD1
  FRT4 ← -WORD1
  FRT5:63 ← WORD2:31 || 290

Denormalized Operand

if WORD1:8 = 0 and WORD9:31 ≠ 0 then
  sign ← WORD0
  exp ← -126
  frac0:52 ← 0b0 || WORD9:31 || 290
  normalize the operand
  do while frac0 = 0
    frac0:52 ← frac1:52 || 0b0

exp ← exp - 1
FRT0 ← sign
FRT1:11 ← exp + 1023
FRT12:63 ← frac1:52

Zero / Infinity / NaN

if WORD1:8 = 255 or WORD1:31 = 0 then
  FRT0:1 ← WORD0:1
  FRT2 ← WORD1
  FRT3 ← WORD1
  FRT4 ← WORD1
  FRT5:63 ← WORD2:31 || 290

For double-precision Load Floating-Point instructions and for the Load Floating-Point as Integer Word Algebraic instruction no conversion is required, as the data from storage are copied directly into the FPR.

Many of the Load Floating-Point instructions have an “update” form, in which register RA is updated with the effective address. For these forms, if RA ≠ 0, the effective address is placed into register RA and the storage element (word or doubleword) addressed by EA is loaded into FRT.

Note: Recall that RA and RB denote General Purpose Registers, while FRT denotes a Floating-Point Register.
**Load Floating-Point Single D-form**

```
Ifs FRT,D(RA)
```

<table>
<thead>
<tr>
<th>0</th>
<th>48</th>
<th>FRT</th>
<th>11</th>
<th>RA</th>
<th>16</th>
<th>D</th>
<th>31</th>
</tr>
</thead>
</table>

if RA = 0 then b ← 0
else b ← (RA)
EA ← b + EXTS(D)
FRT ← DOUBLE(MEM(EA, 4))

Let the effective address (EA) be the sum (RA|0)+D.
The word in storage addressed by EA is interpreted as a floating-point single-precision operand. This word is converted to floating-point double format (see page 133) and placed into register FRT.

**Special Registers Altered:**
None

---

**Load Floating-Point Single Indexed X-form**

```
Ifsx FRT,RA,RB
```

<table>
<thead>
<tr>
<th>0</th>
<th>31</th>
<th>FRT</th>
<th>11</th>
<th>RA</th>
<th>16</th>
<th>RB</th>
<th>535</th>
<th>1</th>
</tr>
</thead>
</table>

if RA = 0 then b ← 0
else b ← (RA)
EA ← b + (RB)
FRT ← DOUBLE(MEM(EA, 4))

Let the effective address (EA) be the sum (RA|0)+(RB).
The word in storage addressed by EA is interpreted as a floating-point single-precision operand. This word is converted to floating-point double format (see page 133) and placed into register FRT.

**Special Registers Altered:**
None

---

**Load Floating-Point Single with Update D-form**

```
Ifsu FRT,D(RA)
```

<table>
<thead>
<tr>
<th>0</th>
<th>49</th>
<th>FRT</th>
<th>11</th>
<th>RA</th>
<th>16</th>
<th>D</th>
<th>31</th>
</tr>
</thead>
</table>

EA ← (RA) + EXTS(D)
FRT ← DOUBLE(MEM(EA, 4))
RA ← EA

Let the effective address (EA) be the sum (RA)+D.
The word in storage addressed by EA is interpreted as a floating-point single-precision operand. This word is converted to floating-point double format (see page 133) and placed into register FRT.
EA is placed into register RA.

If RA=0, the instruction form is invalid.

**Special Registers Altered:**
None

---

**Load Floating-Point Single with Update Indexed X-form**

```
Ifsux FRT,RA,RB
```

<table>
<thead>

### 4.6.3 Floating-Point Store Instructions

There are three basic forms of store instruction: single-precision, double-precision, and integer. The integer form is provided by the `Store Floating-Point as Integer Word` instruction, described on page 140. Because the FPRs support only floating-point double format for floating-point data, single-precision `Store Floating-Point` instructions convert double-precision data to single format prior to storing the operand into storage. The conversion steps are as follows.

Let \( \text{WORD}_{0:31} \) be the word in storage written to.

**No Denormalization Required (includes Zero / Infinity / NaN)**

if \( \text{FRS}_{1:11} > 896 \) or \( \text{FRS}_{1:63} = 0 \) then

\[
\begin{align*}
\text{WORD}_{0:1} & \leftarrow \text{FRS}_{0:1} \\
\text{WORD}_{2:31} & \leftarrow \text{FRS}_{5:34}
\end{align*}
\]

**Denormalization Required**

if \( 874 \leq \text{FRS}_{1:11} \leq 896 \) then

\[
\begin{align*}
\text{sign} & \leftarrow \text{FRS}_{0} \\
\text{exp} & \leftarrow \text{FRS}_{1:11} - 1023 \\
\text{frac}_{0:52} & \leftarrow 0b1 || \text{FRS}_{12:63} \\
\text{denormalize operand} & \text{do while exp} < -126 \\
& \quad \text{frac}_{0:52} \leftarrow 0b0 || \text{frac}_{0:51} \\
& \quad \text{exp} \leftarrow \text{exp} + 1 \\
\text{WORD}_{0} & \leftarrow \text{sign} \\
\text{WORD}_{1:8} & \leftarrow 0x00 \\
\text{WORD}_{9:31} & \leftarrow \text{frac}_{1:23}
\end{align*}
\]

else \( \text{WORD} \leftarrow \text{undefined} \)

Notice that if the value to be stored by a single-precision `Store Floating-Point` instruction is larger in magnitude than the maximum number representable in single format, the first case above (No Denormalization Required) applies. The result stored in \( \text{WORD} \) is then a well-defined value, but is not numerically equal to the value in the source register (i.e., the result of a single-precision `Load Floating-Point` from \( \text{WORD} \) will not compare equal to the contents of the original source register).

For double-precision `Store Floating-Point` instructions and for the `Store Floating-Point as Integer Word` instruction no conversion is required, as the data from the FPR are copied directly into storage.

Many of the `Store Floating-Point` instructions have an “update” form, in which register RA is updated with the effective address. For these forms, if \( \text{RA} \neq 0 \), the effective address is placed into register RA.

**Note:** Recall that RA and RB denote General Purpose Registers, while FRS denotes a Floating-Point Register.
### Store Floating-Point Single D-form

stfs FRS,D(RA)

<table>
<thead>
<tr>
<th></th>

</thead>
</table>

if RA = 0 then b ← 0
else           b ← (RA)
EA ← b + (RB)
MEM(EA, 4) ← (FRS)_{32:63}

Let the effective address (EA) be the sum (RA)(0)+(RB).

(FRS)_{32:63} are stored, without conversion, into the word in storage addressed by EA.

If the contents of register FRS were produced, either directly or indirectly, by a Load Floating-Point Single instruction, a single-precision Arithmetic instruction, or \texttt{frsp}, then the value stored is undefined. (The contents of register FRS are produced directly by such an instruction if FRS is the target register for the instruction. The contents of register FRS are produced indirectly by such an instruction if FRS is the final target register of a sequence of one or more Floating-Point Move instructions, with the input to the sequence having been produced directly by such an instruction.)

Special Registers Altered:
None
4.6.4 Floating-Point Load Store Doubleword Pair Instructions [Category: Floating-Point.Phased-Out]

For \textit{lfdp[x]}, the doubleword-pair in storage addressed by EA is loaded into an even-odd pair of FPRs with the even-numbered FPR being loaded with the leftmost doubleword from storage and the odd-numbered FPR being loaded with the rightmost doubleword.

For \textit{stfdp[x]}, the content of an even-odd pair of FPRs is stored into the doubleword-pair in storage addressed by EA, with the even-numbered FPR being stored into the leftmost doubleword in storage and the odd-numbered FPR being stored into the rightmost doubleword.

---

**Programming Note**

The instructions described in this section should not be used to access an operand in DFP128 format when LE $\neq$ SLE.

---

### Load Floating-Point Double Pair DS-form

\begin{itemize}
  \item \textbf{If} RA = 0 then b $\leftarrow$ 0
  \item else b $\leftarrow$ (RA)
  \item EA $\leftarrow$ b + EXTS(DS||0b00)
  \item FRTp $\leftarrow$ MEM(EA, 16)
\end{itemize}

Let the effective address (EA) be the sum (RA|0) + (DS||0b00). The doubleword-pair in storage addressed by EA is placed into register-pair FRTp.

If FRTp is odd, the instruction form is invalid.

4.6.5 Floating-Point Move Instructions

These instructions copy data from one floating-point register to another, altering the sign bit (bit 0) as described below for \texttt{fneg}, \texttt{fabs}, \texttt{fnabs}, and \texttt{fcpsgn}. These instructions treat NaNs just like any other kind of value (e.g., the sign bit of a NaN may be altered by \texttt{fneg}, \texttt{fabs}, \texttt{fnabs}, and \texttt{fcpsgn}). These instructions do not alter the FPSCR.

### Floating Move Register X-form

\begin{verbatim}

4.6.6 Floating-Point Arithmetic Instructions

4.6.6.1 Floating-Point Elementary Arithmetic Instructions

**Floating Add [Single] A-form**

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fadd</td>
<td>FRT,FRA,FRB (Rc=0)</td>
<td>Floating Add [Single] A-form</td>
</tr>
<tr>
<td>fadd.</td>
<td>FRT,FRA,FRB (Rc=1)</td>
<td>Floating Add [Single] A-form</td>
</tr>
</tbody>
</table>

The floating-point operand in register FRA is added to the floating-point operand in register FRB.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of the Floating-Point Rounding Control field RN of the FPSCR and placed into register FRT.

Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

If a carry occurs, the sum’s significand is shifted right one bit position and the exponent is increased by one.

FPSCR<sub>FPRF</sub> is set to the class and sign of the result, except for Invalid Operation Exceptions when FPSCR<sub>VE</sub>=1.

**Special Registers Altered:**
- FPRF FR FI
- FX OX UX XX
- VXSNAN VXISI
- CR1 (if Rc=1)

---

**Floating Subtract [Single] A-form**

<table>
<thead>
<tr>
<th>Instruction</th>

</thead>
<tbody>
<tr>
<td>fsub</td>
<td>FRT,FRA,FRB (Rc=0)</td>
<td>Floating Subtract [Single] A-form</td>
</tr>
<tr>
<td>fsub.</td>
<td>FRT,FRA,FRB (Rc=1)</td>
<td>Floating Subtract [Single] A-form</td>
</tr>
</tbody>
</table>

The floating-point operand in register FRB is subtracted from the floating-point operand in register FRA.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of the Floating-Point Rounding Control field RN of the FPSCR and placed into register FRT.

The execution of the Floating Subtract instruction is identical to that of Floating Add, except that the contents of FRB participate in the operation with the sign bit (bit 0) inverted.

FPSCR<sub>FPRF</sub> is set to the class and sign of the result, except for Invalid Operation Exceptions when FPSCR<sub>VE</sub>=1.

**Special Registers Altered:**
- FPRF FR FI
- FX OX UX XX
- VXSNAN VXISI
- CR1 (if Rc=1)
### Floating Multiply [Single] A-form

<table>
<thead>
<tr>
<th>Operation</th>
<th>Format</th>
<th>Rounding Control</th>
</tr>
</thead>
<tbody>
<tr>
<td>fmul</td>
<td>FRT,FRA,FRC</td>
<td>Rc=0</td>
</tr>
<tr>
<td>fmul.</td>
<td>FRT,FRA,FRC</td>
<td>Rc=1</td>
</tr>
</tbody>
</table>

The floating-point operand in register FRA is multiplied by the floating-point operand in register FRC.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of the Floating-Point Rounding Control field RN of the FPSCR and placed into register FRT.

Floating-point multiplication is based on exponent addition and multiplication of the significands.

FPSCR<sub>FPRF</sub> is set to the class and sign of the result, except for Invalid Operation Exceptions when FPSCR<sub>VE</sub>=1.

**Special Registers Altered:**
- FPRF  FR  FI
- FX  OX  UX  XX

<td>fdiv</td>
<td>FRT,FRA,FRB</td>
<td>Rc=0</td>
</tr>
<tr>
<td>fdiv.</td>
<td>FRT,FRA,FRB</td>
<td>Rc=1</td>
</tr>
</tbody>
</table>

The floating-point operand in register FRA is divided by the floating-point operand in register FRB. The remainder is not supplied as a result.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of the Floating-Point Rounding Control field RN of the FPSCR and placed into register FRT.

Floating-point division is based on exponent subtraction and division of the significands.

FPSCR<sub>FPRF</sub> is set to the class and sign of the result, except for Invalid Operation Exceptions when FPSCR<sub>VE</sub>=1 and Zero Divide Exceptions when FPSCR<sub>ZE</sub>=1.

**Special Registers Altered:**
- FPRF  FR  FI
- FX  OX  UX  ZX  XX

Let $e_a$ be the unbiased exponent of the double-precision floating-point operand in register FRA.

Let $e_b$ be the unbiased exponent of the double-precision floating-point operand in register FRB.

$fe\_flag$ is set to 1 if any of the following conditions occurs.

- The double-precision floating-point operand in register FRA is a NaN or an Infinity.
- The double-precision floating-point operand in register FRB is a Zero, a NaN, or an Infinity.
- $e_b$ is less than or equal to -1022.
- $e_b$ is greater than or equal to 1021.
- The double-precision floating-point operand in register FRA is not a zero and the difference, $e_a - e_b$, is greater than or equal to 1023.
- The double-precision floating-point operand in register FRA is not a zero and the difference, $e_a - e_b$, is less than or equal to -1021.
- The double-precision floating-point operand in register FRA is not a zero and $e_a$ is less than or equal to -970.

Otherwise $fe\_flag$ is set to 0.

$fg\_flag$ is set to 1 if either of the following conditions occurs.

- The double-precision floating-point operand in register FRA is an Infinity.
- The double-precision floating-point operand in register FRB is a Zero, an Infinity, or a denormalized value.

Otherwise $fg\_flag$ is set to 0.

If the implementation guarantees a relative error of $fre_{\text{rel}}$[.] of less than or equal to $2^{-14}$, then $fl\_flag$ is set to 1. Otherwise $fl\_flag$ is set to 0.

CR field BF is set to the value $fl\_flag || fg\_flag || fe\_flag || 0b0$.

Special Registers Altered:
- CR field BF

Programming Note

$ftdiv$ and $ftsqrt$ are provided to accelerate software emulation of divide and square root operations, by performing the requisite special case checking. Software needs only a single branch, on FE=1 (in CR[BF]), to a special case handler. FG and FL may provide further acceleration opportunities.

4.6.6.2 Floating-Point Multiply-Add Instructions

These instructions combine a multiply and an add operation without an intermediate rounding operation. The fraction part of the intermediate product is 106 bits wide (L bit, FRACTION), and all 106 bits take part in the add/subtract portion of the instruction.

Status bits are set as follows.
- Overflow, Underflow, and Inexact Exception bits, the FR and FI bits, and the FPRF field are set based on the final result of the operation, and not on the result of the multiplication.
- Invalid Operation Exception bits are set as if the multiplication and the addition were performed using two separate instructions (fmu[s], followed by fadd[s] or fsub[s]). That is, multiplication of infinity by 0 or of anything by an SNaN, and/or addition of an SNaN, cause the corresponding exception bits to be set.

### Floating Multiply-Add [Single] A-form

<table>
<thead>
<tr>
<th>Operation</th>

Floating Negative Multiply-Add [Single] A-form

fnmadd FRT,FRA,FRC,FRB (Rc=0)
fnmadd. FRT,FRA,FRC,FRB (Rc=1)

fnmadds FRT,FRA,FRC,FRB (Rc=0)
fnmadds. FRT,FRA,FRC,FRB (Rc=1)

The operation

\[
\text{FRT} \leftarrow - \left( \left( \text{FRA} \times \text{FRC} \right) + \text{FRB} \right)
\]

is performed.

The floating-point operand in register FRA is multiplied by the floating-point operand in register FRC. The floating-point operand in register FRB is added to this intermediate result.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of the Floating-Point Rounding Control field RN of the FPSCR, then negated and placed into register FRT.

This instruction produces the same result as would be obtained by using the Floating Multiply-Add instruction and then negating the result, with the following exceptions.

- QNaNs propagate with no effect on their “sign” bit.
- QNaNs that are generated as the result of a disabled Invalid Operation Exception have a “sign” bit of 0.
- SNaNs that are converted to QNaNs as the result of a disabled Invalid Operation Exception retain the “sign” bit of the SNaN.

FPSCR\text{FPRF} is set to the class and sign of the result, except for Invalid Operation Exceptions when FPSCR\text{VE}=1.

Special Registers Altered:

\[
\begin{array}{llllllll}
\text{FPRF} & \text{FR} & \text{FI} & \text{FX} & \text{OX} & \text{UX} & \text{XX} & \text{VXSNAN} & \text{VXISI} & \text{VXIMZ} & \text{CR1} \\
\end{array}
\]

(if Rc=1)

Floating Negative Multiply-Subtract [Single] A-form

fnmsub FRT,FRA,FRC,FRB (Rc=0)
fnmsub. FRT,FRA,FRC,FRB (Rc=1)

fnmsubs FRT,FRA,FRC,FRB (Rc=0)
fnmsubs. FRT,FRA,FRC,FRB (Rc=1)

The operation

\[
\text{FRT} \leftarrow - \left( \left( \text{FRA} \times \text{FRC} \right) - \text{FRB} \right)
\]

is performed.

The floating-point operand in register FRA is multiplied by the floating-point operand in register FRC. The floating-point operand in register FRB is subtracted from this intermediate result.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of the Floating-Point Rounding Control field RN of the FPSCR, then negated and placed into register FRT.

This instruction produces the same result as would be obtained by using the Floating Multiply-Subtract instruction and then negating the result, with the following exceptions.

- QNaNs propagate with no effect on their “sign” bit.
- QNaNs that are generated as the result of a disabled Invalid Operation Exception have a “sign” bit of 0.
- SNaNs that are converted to QNaNs as the result of a disabled Invalid Operation Exception retain the “sign” bit of the SNaN.

FPSCR\text{FPRF} is set to the class and sign of the result, except for Invalid Operation Exceptions when FPSCR\text{VE}=1.

Special Registers Altered:

\[
\begin{array}{llllllll}
\text{FPRF} & \text{FR} & \text{FI} & \text{FX} & \text{OX} & \text{UX} & \text{XX} & \text{VXSNAN} & \text{VXISI} & \text{VXIMZ} & \text{CR1} \\
\end{array}
\]

(if Rc=1)
4.6.7 Floating-Point Rounding and Conversion Instructions

### 4.6.7.1 Floating-Point Rounding Instruction

**Floating Round to Single-Precision X-form**

<table>
<thead>

</tbody>
</table>

Let src be the double-precision floating-point value in FRB.

If src is a NaN, then the result is 0x8000_0000_0000_0000, VXCVI is set to 1, and, if src is an SNaN, VXSNAN is set to 1.

Otherwise, src is rounded to a floating-point integer using the rounding mode specified by FPSCRRN.

If the rounded value is greater than $2^{63}-1$, then the result is 0x7FFF_FFFF_FFFF_FFFF and VXCVI is set to 1.

Otherwise, if the rounded value is less than $-2^{63}$, then the result is 0x8000_0000_0000_0000 and VXCVI is set to 1.

Otherwise, the result is the rounded value converted to 64-bit signed-integer format.

If an enabled Invalid Operation Exception does not occur, then the result is placed into FRT.

The conversion is described fully in Section A.2, “Floating-Point Convert to Integer Model” on page 689.

Except for enabled Invalid Operation Exceptions, FPSCR_{FPRC} is undefined. FPSCR_{FR} is set if the result is incremented when rounded. FPSCR_{FI} is set if the result is inexact.

**Special Registers Altered:**

Programming Note

Converting a unsigned integer word to single-precision floating-point can be accomplished by loading the word from storage using Load Float Word and Zero Indexed and then using fccfidus.

4.6.7.3 Floating Round to Integer Instructions

The Floating Round to Integer instructions provide direct support for rounding functions found in high level languages. For example, frin, friz, frip, and frim implement C++ round(), trunc(), ceil(), and floor(), respectively. Note that frin does not implement the IEEE Round to Nearest function, which is often further described as “ties to even.” The rounding performed by these instructions is described fully in Section A.4, “Floating-Point Round to Integer Model” on page 694.

Programming Note

These instructions set FPSCR_FR1 to 0b00 regardless of whether the result is inexact or rounded because there is a desire to preserve the value of FPSCR_XX. Furthermore, it is believed that most programs do not need to know whether these rounding operations produce inexact or rounded results. If it is necessary to determine whether the result is inexact or rounded, software must compare the result with the original source operand.
Floating Round to Integer Nearest X-form

frin  FRT,FRB  (Rc=0)
frin. FRT,FRB  (Rc=1)

<table>
<thead>
<tr>
<th>63</th>
<th>FRT</th>

</tbody>
</table>

The floating-point operand in register FRB is rounded to an integral value using the rounding mode round toward -infinity, and the result is placed into register FRT.

FPSCR_{FPRF} is set to the class and sign of the result, except for Invalid Operation Exceptions when FPSCR_{VE} = 1.

Special Registers Altered:
- FPRF FR (set to 0) FI (set to 0)
- FX
- VXSNAN
- CR1 (if Rc = 1)
4.6.8 Floating-Point Compare Instructions

The floating-point Compare instructions compare the contents of two floating-point registers. Comparison ignores the sign of zero (i.e., regards +0 as equal to −0). The comparison can be ordered or unordered.

The comparison sets one bit in the designated CR field to 1 and the other three to 0. The CR is set in the same way.

**Floating Compare Unordered X-form**

```
fcmpu BF,FRA,FRB
```

<table>
<thead>
<tr>
<th>CR field BF</th>
<th>63</th>
<th>BF // FRA</th>
<th>16</th>
<th>21</th>
<th>0</th>
<th>/</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>if (FRA) is a NaN or (FRB) is a NaN then c ← 0b0001</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>else if (FRA) &lt; (FRB) then c ← 0b1000</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>else if (FRA) &gt; (FRB) then c ← 0b0100</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>else</td>
<td>c ← 0b0010</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>FPCC ← c</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CR4×BF:4×BF+3 ← c</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>if (FRA) is an SNaN or (FRB) is an SNaN then VXSNAN ← 1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The floating-point operand in register FRA is compared to the floating-point operand in register FRB. The result of the compare is placed into CR field BF and the FPCC.

If either of the operands is a NaN, either quiet or signaling, then CR field BF and the FPCC are set to reflect unordered. If either of the operands is a Signaling NaN, then VXSNAN is set.

**Special Registers Altered:**
- CR field BF
- FPCC
- FX
- VXSNAN

**Floating Compare Ordered X-form**

```
fcmpo BF,FRA,FRB
```

<table>
<thead>
<tr>
<th>CR field BF</th>
<th>63</th>
<th>BF // FRA</th>
<th>16</th>
<th>21</th>
<th>32</th>
<th>/</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>

<tr>
<td>else if (FRA) is a QNaN or (FRB) is a QNaN then VXVC ← 1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The floating-point operand in register FRA is compared to the floating-point operand in register FRB. The result of the compare is placed into CR field BF and the FPCC.

If either of the operands is a NaN, either quiet or signaling, then CR field BF and the FPCC are set to reflect unordered. If either of the operands is a Signaling NaN, then VXSNAN is set and, if Invalid Operation is disabled (VE=0), VXVC is set. If neither operand is a Signaling NaN but at least one operand is a Quiet NaN, then VXVC is set.

**Special Registers Altered:**
- CR field BF
- FPCC
- FX
- VXSNAN
- VXVC
4.6.9 Floating-Point Select Instruction

Floating Select A-form

\[
\text{fsel} \quad \text{FRT}, \text{FRA}, \text{FRC}, \text{FRB} \quad \text{(Rc}=0) \\
\text{fsel.} \quad \text{FRT}, \text{FRA}, \text{FRC}, \text{FRB} \quad \text{(Rc}=1)
\]

\[
\begin{array}{cccccc}
0 & 63 & 6 & 11 & 16 & 21 & 23 & 26 & 31 \\
\text{FRT} & \text{FRA} & \text{FRB} & \text{FRC} & \text{Rc}
\end{array}
\]

if \((\text{FRA}) \geq 0.0\) then \(\text{FRT} \leftarrow (\text{FRC})\)  \\
else \(\text{FRT} \leftarrow (\text{FRB})\)

The floating-point operand in register FRA is compared to the value zero. If the operand is greater than or equal to zero, register FRT is set to the contents of register FRC. If the operand is less than zero or is a NaN, register FRT is set to the contents of register FRB. The comparison ignores the sign of zero (i.e., regards \(+0\) as equal to \(-0\)).

Special Registers Altered:  
CR1  
(if Rc=1)

Programming Note

Examples of uses of this instruction can be found in Sections F.2, “Floating-Point Conversions [Category: Floating-Point]” on page 726 and F.3, “Floating-Point Selection [Category: Floating-Point]” on page 730.

Warning: Care must be taken in using \text{fsel} if IEEE compatibility is required, or if the values being tested can be NaNs or infinities; see Section F.3.4, “Notes” on page 730.
4.6.10 Floating-Point Status and Control Register Instructions

Every Floating-Point Status and Control Register instruction synchronizes the effects of all floating-point instructions executed by a given processor. Executing a Floating-Point Status and Control Register instruction ensures that all floating-point instructions previously initiated by the given processor have completed before the Floating-Point Status and Control Register instruction is initiated, and that no subsequent floating-point instructions are initiated by the given processor until the Floating-Point Status and Control Register instruction has completed. In particular:

- All exceptions that will be caused by the previously initiated instructions are recorded in the FPSCR before the Floating-Point Status and Control Register instruction is initiated.
- All invocations of the system floating-point enabled exception error handler that will be caused by the previously initiated instructions have occurred before the Floating-Point Status and Control Register instruction is initiated.
- No subsequent floating-point instruction that depends on or alters the settings of any FPSCR bits is initiated until the Floating-Point Status and Control Register instruction has completed.

(Floating-point Storage Access instructions are not affected.)

The instruction descriptions in this section refer to "FPSCR fields," where FPSCR field k is FPSCR bits 4xk:4xk+3.

Move From FPSCR X-form

<table>
<thead>
<tr>

<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>FRT</td>
</tr>
<tr>
<td>6</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td></td>
</tr>
<tr>
<td>16</td>
<td></td>
</tr>
<tr>
<td>21</td>
<td>Rc</td>
</tr>
<tr>
<td>31</td>
<td></td>
</tr>
</tbody>
</table>

The contents of the FPSCR are placed into register FRT.

Special Registers Altered:
- CR1 (if Rc=1)

Move to Condition Register from FPSCR X-form

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mcrfs BF,BFA</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>63</td>
<td>BF</td>
</tr>
<tr>
<td>6</td>
<td></td>
</tr>
<tr>
<td>9</td>
<td>BFA</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>16</td>
<td></td>
</tr>
<tr>
<td>21</td>
<td></td>
</tr>
<tr>
<td>31</td>
<td></td>
</tr>
</tbody>
</table>

The contents of FPSCR_{32:63} field BFA are copied to Condition Register field BF. All exception bits copied are set to 0 in the FPSCR. If the FX bit is copied, it is set to 0 in the FPSCR.

Special Registers Altered:
- CR field BF
  - FX OX (if BFA=0)
  - UX ZX XX VXSNAN (if BFA=1)
  - VXISI VXIDI VXZDZ VXIMZ (if BFA=2)
  - VXVC (if BFA=3)
  - VXSOFT VXSQRT VXCVI (if BFA=5)
Move To FPSCR Field Immediate X-form

mtfsfi BF,U,W (Rc=0)
mtfsfi BF,U,W (Rc=1)

The value of the U field is placed into FPSCR field BF+8×(1-W).
FPSCR_FX is altered only if BF = 0 and W = 0.

Special Registers Altered:
FPSCR field BF + 8×(1-W)
CR1 (if Rc=1)

--- Programming Note ---

mtfsfi serves as both a basic and an extended mnemonic. The Assembler will recognize a mtfsfi mnemonic with three operands as the basic form, and a mtfsfi mnemonic with two operands as the extended form. In the extended form the W operand is omitted and assumed to be 0.

--- Programming Note ---

When FPSCR_{32:35} is specified, bits 32 (FX) and 35 (OX) are set to the values of U_3 and U_2 (i.e., even if this instruction causes OX to change from 0 to 1, FX is set from U_3 and not by the usual rule that FX is set to 1 when an exception bit changes from 0 to 1). Bits 33 and 34 (FEX and VX) are set according to the usual rule, given on page 117, and not from U_{1:2}.

Move To FPSCR Fields XFL-form

mtfsf FLM,FRB,L,W (Rc=0)
mtfsf FLM,FRB,L,W (Rc=1)

The FPSCR is modified as specified by the FLM, L, and W fields.

L = 0
The contents of register FRB are placed into the FPSCR under control of the W field and the field mask specified by FLM. W and the field mask identify the 4-bit fields affected. Let i be an integer in the range 0-7. If FLM_i=1 then FPSCR field k is set to the contents of the corresponding field of register FRB, where k = i+8×(1-W).

L = 1
The contents of register FRB are placed into the FPSCR.
FPSCR_FX is not altered implicitly by this instruction.

Special Registers Altered:
FPSCR fields selected by mask, L, and W
CR1 (if Rc=1)

--- Programming Note ---

mtfsf serves as both a basic and an extended mnemonic. The Assembler will recognize a mtfsf mnemonic with four operands as the basic form, and a mtfsf mnemonic with two operands as the extended form. In the extended form the W and L operands are omitted and both are assumed to be 0.

--- Programming Note ---

Updating fewer than eight fields of the FPSCR may have substantially poorer performance on some implementations than updating eight fields or all of the fields.

--- Programming Note ---

If L=1 or if L=0 and FPSCR_{32:35} is specified, bits 32 (FX) and 35 (OX) are set to the values of (FRB)_{32} and (FRB)_{35} (i.e., even if this instruction causes OX to change from 0 to 1, FX is set from (FRB)_{32} and not by the usual rule that FX is set to 1 when an exception bit changes from 0 to 1). Bits 33 and 34 (FEX and VX) are set according to the usual rule, given on page 117, and not from (FRB)_{33:34}.
### Move To FPSCR Bit 0 X-form

<table>
<thead>
<tr>
<th>mtsfb0</th>
<th>BT</th>
<th>(Rc=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtsfb0.</td>
<td>BT</td>
<td>(Rc=1)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>63</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>70</th>
<th>Rc</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>63</td>
<td></td>
</tr>
</tbody>
</table>

Bit BT+32 of the FPSCR is set to 0.

**Special Registers Altered:**
- FPSCR bit BT+32
- CR1 (if Rc=1)

**Programming Note**
Bits 33 and 34 (FEX and VX) cannot be explicitly reset.

### Move To FPSCR Bit 1 X-form

<table>
<thead>
<tr>
<th>mtsfb1</th>
<th>BT</th>
<th>(Rc=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtsfb1.</td>
<td>BT</td>
<td>(Rc=1)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>63</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>38</th>
<th>Rc</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>63</td>
<td></td>
</tr>
</tbody>
</table>

Bit BT+32 of the FPSCR is set to 1.

**Special Registers Altered:**
- FPSCR bits BT+32 and FX
- CR1 (if Rc=1)

**Programming Note**
Bits 33 and 34 (FEX and VX) cannot be explicitly set.
Chapter 5. Vector Facility [Category: Vector]

5.1 Vector Facility Overview

This chapter describes the registers and instructions that make up the Vector Facility.

5.2 Chapter Conventions

5.2.1 Description of Instruction Operation

The following notation, in addition to that described in Section 1.3.2, is used in this chapter. Additional RTL functions are described in Appendix C.

- $x.bit[y]$  
  Return the contents of bit $y$ of $x$.

- $x.bit[y:z]$  
  Return the contents of bits $y:z$ of $x$.

- $x.byte[y]$  
  Return the contents of byte element $y$ of $x$.

- $x.byte[y:z]$  
  Return the contents of byte elements $y:z$ of $x$.

- $x.hword[y]$  
  Return the contents of halfword element $y$ of $x$.

- $x.hword[y:z]$  
  Return the contents of halfword elements $y:z$ of $x$.

- $x.word[y]$  
  Return the contents of word element $y$ of $x$.

- $x.word[y:z]$  
  Return the contents of word element $y:z$ of $x$.

- $x.dword[y:z]$  
  Return the contents of doubleword elements $y:z$ of $x$.

- $x ? y : z$  
  If the value of $x$ is true, then the value of $y$, otherwise the value $z$.

- $^+_int$  
  Integer addition.

- $^+_fp$  
  Floating-point addition.

- $^-fp$  
  Floating-point subtraction.

- $x_{sui}$  
  Multiplication of a signed-integer (first operand) by an unsigned-integer (second operand).

- $x_{fp}$  
  Floating-point multiplication.

- $=_{int}$  
  Integer equals relation.

- $=_{fp}$  
  Floating-point equals relation.

- $<_{ui}$, $\leq_{ui}$, $>_{ui}$, $\geq_{ui}$  
 Unsigned-integer comparison relations.

- $<_{si}$, $\leq_{si}$, $>_{si}$, $\geq_{si}$  
  Signed-integer comparison relations.

- $<_{fp}$, $\leq_{fp}$, $>_{fp}$, $\geq_{fp}$  
  Floating-point comparison relations.

- $LENGTH(x)$  
  Length of $x$, in bits. If $x$ is the word “element”, $LENGTH(x)$ is the length, in bits, of the element implied by the instruction mnemonic.
\( x \ll y \)
Result of shifting \( x \) left by \( y \) bits, filling vacated bits with zeros.
\[
b \leftarrow \text{LENGTH}(x) \\
\text{result} \leftarrow (y < b) \ ? \ (x_{y:b-1} \lor 0) : b_0
\]

\( x \gg y \)
Result of shifting \( x \) right by \( y \) bits, filling vacated bits with zeros.
\[
b \leftarrow \text{LENGTH}(x) \\
\text{result} \leftarrow (y < b) \ ? \ (0 \| x_{(b-y):b-1}) : b_0
\]

\( x \ggg y \)
Result of shifting \( x \) right by \( y \) bits, filling vacated bits with copies of bit 0 (sign bit) of \( x \).
\[
b \leftarrow \text{LENGTH}(x) \\
\text{result} \leftarrow (y < b) \ ? \ (\bar{y}_0 \| x_{(b-y):b-1}) : b_0
\]

\( x \lll y \)
Result of rotating \( x \) left by \( y \) bits.
\[
b \leftarrow \text{LENGTH}(x) \\
\text{result} \leftarrow x_{y:b-1} \lor x_{y:0}
\]

\( x \ggg y \)
Returns the contents of \( x \) rotated right by \( y \) bits.

\( \text{Chop}(x, y) \)
Result of extending the right-most \( y \) bits of \( x \) on the left with zeros.
\[
\text{result} \leftarrow x \& ((1<y)-1)
\]

\( \text{EXTZ}(x) \)
Result of extending \( x \) on the left with zeros.
\[
b \leftarrow \text{LENGTH}(x) \\
\text{result} \leftarrow x \& ((1<b)-1)
\]

\( \text{Clamp}(x, y, z) \)
x is interpreted as a signed integer. If the value of \( x \) is less than \( y \), then the value \( y \) is returned, else if the value of \( x \) is greater than \( z \), the value \( z \) is returned, else the value \( x \) is returned.
\[
\text{if} \ (x < y) \ \text{then} \\
\text{result} \leftarrow y \\
\text{VSCRSAT} \leftarrow 1 \\
\text{else if} \ (x > z) \ \text{then} \\
\text{result} \leftarrow z \\
\text{VSCRSAT} \leftarrow 1 \\
\text{else result} \leftarrow x
\]

\( \text{InvMixColumns}(x) \)
\[
do \ c = 0 \ to \ 3 \\
\text{result}.\text{word}[c].\text{byte}[0] = 0x0E \times \text{word}[c].\text{byte}[0] \ ^ \ 0x0B \times \text{word}[c].\text{byte}[1] \ ^ \ 0x0D \times \text{word}[c].\text{byte}[2] \ ^ \ 0x09 \times \text{word}[c].\text{byte}[3] \\
\text{result}.\text{word}[c].\text{byte}[1] = 0x09 \times \text{word}[c].\text{byte}[0] \ ^ \ 0x0E \times \text{word}[c].\text{byte}[1] \ ^ \ 0x0B \times \text{word}[c].\text{byte}[2] \ ^ \ 0x0D \times \text{word}[c].\text{byte}[3] \\
\text{result}.\text{word}[c].\text{byte}[2] = 0x0D \times \text{word}[c].\text{byte}[0] \ ^ \ 0x09 \times \text{word}[c].\text{byte}[1] \ ^ \ 0x0E \times \text{word}[c].\text{byte}[2] \ ^ \ 0x0B \times \text{word}[c].\text{byte}[3] \\
\text{result}.\text{word}[c].\text{byte}[3] = 0x0B \times \text{word}[c].\text{byte}[0] \ ^ \ 0x0D \times \text{word}[c].\text{byte}[1] \ ^ \ 0x09 \times \text{word}[c].\text{byte}[2] \ ^ \ 0x0E \times \text{word}[c].\text{byte}[3] \\
\text{end} \\
\text{return}(\text{result});
\]

where “\(^\times\)" is a GF(2^8) multiply, a binary polynomial multiplication reduced by modulo \(0x11b\).

The GF(2^8) multiply of \(0x09\times x\) can be expressed in minimized terms as the following.
\[
\text{product}.\text{bit}[0] = x.\text{bit}[0] \ ^ \ x.\text{bit}[3] \\
\text{product}.\text{bit}[1] = x.\text{bit}[1] \ ^ \ x.\text{bit}[4] \ ^ \ x.\text{bit}[0] \\
\text{product}.\text{bit}[2] = x.\text{bit}[2] \ ^ \ x.\text{bit}[5] \ ^ \ x.\text{bit}[0] \ ^ \ x.\text{bit}[1] \\
\text{product}.\text{bit}[3] = x.\text{bit}[3] \ ^ \ x.\text{bit}[6] \ ^ \ x.\text{bit}[0] \ ^ \ x.\text{bit}[1] \ ^ \ x.\text{bit}[2] \\
\text{product}.\text{bit}[4] = x.\text{bit}[4] \ ^ \ x.\text{bit}[7] \ ^ \ x.\text{bit}[0] \\
\text{product}.\text{bit}[5] = x.\text{bit}[5] \ ^ \ x.\text{bit}[0] \ ^ \ x.\text{bit}[1] \\
\text{product}.\text{bit}[6] = x.\text{bit}[6] \ ^ \ x.\text{bit}[1] \ ^ \ x.\text{bit}[2] \\
\text{product}.\text{bit}[7] = x.\text{bit}[7] \ ^ \ x.\text{bit}[2]
\]

The GF(2^8) multiply of \(0x0b\times x\) can be expressed in minimized terms as the following.
\[
\text{product}.\text{bit}[0] = x.\text{bit}[0] \ ^ \ x.\text{bit}[3] \\
\text{product}.\text{bit}[1] = x.\text{bit}[1] \ ^ \ x.\text{bit}[4] \ ^ \ x.\text{bit}[0] \\
\text{product}.\text{bit}[2] = x.\text{bit}[2] \ ^ \ x.\text{bit}[3] \ ^ \ x.\text{bit}[5] \ ^ \ x.\text{bit}[0] \ ^ \ x.\text{bit}[1] \\
\text{product}.\text{bit}[3] = x.\text{bit}[3] \ ^ \ x.\text{bit}[4] \ ^ \ x.\text{bit}[6] \ ^ \ x.\text{bit}[0] \ ^ \ x.\text{bit}[1] \ ^ \ x.\text{bit}[2] \\
\text{product}.\text{bit}[4] = x.\text{bit}[4] \ ^ \ x.\text{bit}[5] \ ^ \ x.\text{bit}[7] \ ^ \ x.\text{bit}[2] \\
\text{product}.\text{bit}[5] = x.\text{bit}[5] \ ^ \ x.\text{bit}[0] \ ^ \ x.\text{bit}[1] \ ^ \ x.\text{bit}[2] \\
\text{product}.\text{bit}[6] = x.\text{bit}[6] \ ^ \ x.\text{bit}[7] \ ^ \ x.\text{bit}[0] \ ^ \ x.\text{bit}[1] \ ^ \ x.\text{bit}[2] \\
\text{product}.\text{bit}[7] = x.\text{bit}[7] \ ^ \ x.\bit[0] \ ^ \ x.\text{bit}[2]
The GF(2^8) multiply of 0x0D•x can be expressed in minimized terms as the following.

\[
\begin{align*}
\text{product.bit}[0] &= x.\text{bit}[0] \oplus x.\text{bit}[2] \oplus x.\text{bit}[3] \\
\text{product.bit}[1] &= x.\text{bit}[1] \oplus x.\text{bit}[3] \oplus x.\text{bit}[4] \oplus x.\text{bit}[0] \\
\text{product.bit}[2] &= x.\text{bit}[2] \oplus x.\text{bit}[4] \oplus x.\text{bit}[5] \oplus x.\text{bit}[1] \\
\text{product.bit}[3] &= x.\text{bit}[3] \oplus x.\text{bit}[5] \oplus x.\text{bit}[6] \oplus x.\text{bit}[0] \oplus x.\text{bit}[2] \\
\text{product.bit}[4] &= x.\text{bit}[4] \oplus x.\text{bit}[6] \oplus x.\text{bit}[7] \oplus x.\text{bit}[0] \oplus x.\text{bit}[1] \oplus x.\text{bit}[2] \\
\text{product.bit}[5] &= x.\text{bit}[5] \oplus x.\text{bit}[7] \oplus x.\text{bit}[1] \\
\text{product.bit}[6] &= x.\text{bit}[6] \oplus x.\text{bit}[0] \oplus x.\text{bit}[2] \\
\text{product.bit}[7] &= x.\text{bit}[7] \oplus x.\text{bit}[1] \oplus x.\text{bit}[2]
\end{align*}
\]

The GF(2^8) multiply of 0x0E•x can be expressed in minimized terms as the following.

\[
\begin{align*}
\text{product.bit}[0] &= x.\text{bit}[1] \oplus x.\text{bit}[2] \oplus x.\text{bit}[3] \\
\text{product.bit}[1] &= x.\text{bit}[2] \oplus x.\text{bit}[3] \oplus x.\text{bit}[4] \oplus x.\text{bit}[0] \\
\text{product.bit}[2] &= x.\text{bit}[3] \oplus x.\text{bit}[4] \oplus x.\text{bit}[5] \oplus x.\text{bit}[1] \\
\text{product.bit}[3] &= x.\text{bit}[4] \oplus x.\text{bit}[5] \oplus x.\text{bit}[6] \oplus x.\text{bit}[2] \\
\text{product.bit}[4] &= x.\text{bit}[5] \oplus x.\text{bit}[6] \oplus x.\text{bit}[7] \oplus x.\text{bit}[1] \oplus x.\text{bit}[2] \\
\text{product.bit}[5] &= x.\text{bit}[6] \oplus x.\text{bit}[7] \oplus x.\text{bit}[1] \\
\text{product.bit}[6] &= x.\text{bit}[7] \oplus x.\text{bit}[2] \\
\text{product.bit}[7] &= x.\text{bit}[0] \oplus x.\text{bit}[1] \oplus x.\text{bit}[2]
\end{align*}
\]

InvShiftRows(x)

\[
\begin{align*}

return(result)

Signed_BCD_Add(x,y,z)

Let x and y be 31-digit signed decimal values.

Performs a signed decimal addition of x and y.

If the unbounded result is equal to zero, eq_flag is set to 1. Otherwise, eq_flag is set to 0.
If the unbounded result is greater than zero, gt_flag is set to 1. Otherwise, gt_flag is set to 0.
If the unbounded result is less than zero, lt_flag is set to 1. Otherwise, lt_flag is set to 0.

If the magnitude of the unbounded result is greater than \(10^{31}-1\), ox_flag is set to 1. Otherwise, ox_flag is set to 0.

If the unbounded result is greater than or equal to zero, the sign code of the result is set to 0b1100 if z=0.
If the unbounded result is greater than or equal to zero, the sign code of the result is set to 0b1111 if z=1.
If the unbounded result is less than zero, the sign code of the result is set to 0b1101.

The low-order 31 digits of the unbounded result magnitude concatenated with the sign code are returned.

If either operand is an invalid encoding of a signed decimal value, the result returned is undefined and inv_flag is set to 1 and lt_flag, gt_flag and eq_flag are set to 0. Otherwise, inv_flag is set to 0.
Signed_BCD_Subtract(x,y,z)

Let \( x \) and \( y \) be 31-digit signed decimal values.

Performs a signed decimal subtract of \( y \) from \( x \).

If the unbounded result is equal to zero, \( eq \_flag \) is set to 1. Otherwise, \( eq \_flag \) is set to 0.
If the unbounded result is greater than zero, \( gt \_flag \) is set to 1. Otherwise, \( gt \_flag \) is set to 0.
If the unbounded result is less than zero, \( lt \_flag \) is set to 1. Otherwise, \( lt \_flag \) is set to 0.

If the magnitude of the unbounded result is greater than \( 10^{31} \), \( ox \_flag \) is set to 1. Otherwise, \( ox \_flag \) is set to 0.

If the unbounded result is greater than or equal to zero, the sign code of the result is set to 0b1100 if \( z=0 \).
If the unbounded result is greater than or equal to zero, the sign code of the result is set to 0b1111 if \( z=1 \).
If the unbounded result is less than zero, the sign code of the result is set to 0b1101.

The low-order 31 digits of the unbounded result magnitude concatenated with the sign code are returned.

If either operand is an invalid encoding of a signed decimal value, the result returned is undefined and \( inv \_flag \) is set to 0. Otherwise, \( inv \_flag \) is set to 0.

\]
\[
\text{end}
\]
\[
\text{return(result)}
\]

RoundToSPIntCeil(x)

The value \( x \) if \( x \) is a single-precision floating-point integer; otherwise the smallest single-precision floating-point integer that is greater than \( x \).

RoundToSPIntFloor(x)

The value \( x \) if \( x \) is a single-precision floating-point integer; otherwise the largest single-precision floating-point integer that is less than \( x \).

RoundToSPIntNear(x)

The value \( x \) if \( x \) is a single-precision floating-point integer; otherwise the single-precision floating-point integer that is nearest in value to \( x \) (in case of a tie, the even single-precision floating-point integer is used).

RoundToSPIntTrunc(x)

The value \( x \) if \( x \) is a single-precision floating-point integer; otherwise the largest single-precision floating-point integer that is less than \( x \) if \( x>0 \), or the smallest single-precision floating-point integer that is greater than \( x \) if \( x<0 \).

RoundToNearSP(x)

The single-precision floating-point number that is nearest in value to the infinitely-precise floating-point intermediate result \( x \) (in case of a tie, the single-precision floating-point value with the least-significant bit equal to 0 is used).
ReciprocalEstimateSP(x)
A single-precision floating-point estimate of the reciprocal of the single-precision floating-point number x.

ReciprocalSquareRootEstimateSP(x)
A single-precision floating-point estimate of the reciprocal of the square root of the single-precision floating-point number x.

LogBase2EstimateSP(x)
A single-precision floating-point estimate of the base 2 logarithm of the single-precision floating-point number x.

Power2EstimateSP(x)
A single-precision floating-point estimate of the 2 raised to the power of the single-precision floating-point number x.

5.3 Vector Facility Registers

5.3.1 Vector Registers

There are 32 Vector Registers (VRs), each containing 128 bits. See Figure 64. All computations and other data manipulation are performed on data residing in Vector Registers, and results are placed into a VR.

![Figure 64. Vector Registers](image)

Depending on the instruction, the contents of a Vector Register are interpreted as a sequence of equal-length elements (bytes, halfwords, or words) or as a quadword. Each of the elements is aligned at its natural boundary within the Vector Register, as shown in Figure 63. Many instructions perform a given operation in parallel on all elements in a Vector Register. Depending on the instruction, a byte, halfword, or word element can be interpreted as a signed-integer, an unsigned-integer, or a logical value; a word element can also be interpreted as a single-precision floating-point value. In the instruction descriptions, phrases like "signed-integer word element" are used as shorthand for "word element, interpreted as a signed-integer".

Load and Store instructions are provided that transfer a byte, halfword, word, or quadword between storage and a Vector Register.

5.3.2 Vector Status and Control Register

The Vector Status and Control Register (VSCR) is a special 32-bit register (not an SPR) that is read and written in a manner similar to the FPSCR in the Power ISA scalar floating-point unit. Special instructions (mvflscr and mtvflscr) are provided to move the VSCR from and to a vector register. When moved to or from a vector register, the 32-bit VSCR is right justified in the 128-bit vector register. When moved to a vector register, bits 0:95 of the vector register are cleared (set to 0).

![Figure 65. Vector Status and Control Register](image)

The bit definitions for the VSCR are as follows.

<td>instruction.</td>
</tr>
</tbody>
</table>
After the `mfvscr` instruction executes, the result in the target vector register will be architecturally precise. That is, it will reflect all updates to the SAT bit that could have been made by vector instructions logically preceding it in the program flow, and further, it will not reflect any SAT updates that may be made to it by vector instructions logically following it in the program flow. To implement this, processors may choose to make the `mfvscr` instruction execute serializing within the vector unit, meaning that it will stall vector instruction execution until all preceding vector instructions are complete and have updated the architectural machine state. This is permitted in order to simplify implementation of the sticky status bit (SAT) which would otherwise be difficult to implement in an out-of-order execution machine. The implication of this is that reading the VSCR can be much slower than typical Vector instructions, and therefore care must be taken in reading it, as advised in Section 5.5.1, to avoid performance problems.

The `mtvscr` is context synchronizing. This implies that all Vector instructions logically preceding an `mtvscr` in the program flow will execute in the architectural context (NJ mode) that existed prior to completion of the `mtvscr`, and that all instructions logically following the `mtvscr` will execute in the new context (NJ mode) established by the `mtvscr`.

### 5.3.3 VR Save Register

The VR Save Register (VRSAVE) is a 32-bit register in the fixed-point processor provided for application and operating system use; see Section 3.2.3.

---

**Programming Note**

The VRSAVE register can be used to indicate which VRs are currently being used by a program. If this is done, the operating system could save only those VRs when an “interrupt” occurs (see Book III), and could restore only those VRs when resuming the interrupted program.

If this approach is taken it must be applied rigorously; if a program fails to indicate that a given VR is in use, software errors may occur that will be difficult to detect and correct because they are timing-dependent.

Some operating systems save and restore VRSAVE only for programs that also use other vector registers.

### 5.4 Vector Storage Access Operations

The Vector Storage Access instructions provide the means by which data can be copied from storage to a Vector Register or from a Vector Register to storage. Instructions are provided that access byte, halfword, word, and quadword storage operands. These instructions differ from the fixed-point and floating-point Storage Access instructions in that vector storage operands are assumed to be aligned, and vector storage accesses are performed as if the appropriate number of low-order bits of the specified effective address (EA) were zero. For example, the low-order bit of EA is ignored for halfword Vector Storage Access instructions, and the low-order four bits of EA are ignored for quadword Vector Storage Access instructions. The effect is to load or store the storage operand of the specified length that contains the byte addressed by EA.

If a storage operand is unaligned, additional instructions must be used to ensure that the operand is correctly placed in a Vector Register or in storage. Instructions are provided that shift and merge the contents of two Vector Registers, such that an unaligned quadword storage operand can be copied between storage and the Vector Registers in a relatively efficient manner.

As shown in Figure 63, the elements in Vector Registers are numbered; the high-order (or most significant) byte element is numbered 0 and the low-order (or least significant) byte element is numbered 15. The numbering affects the values that must be placed into the permute control vector for the Vector Permute instruction in order for that instruction to achieve the desired effects, as illustrated by the examples in the following subsections.

A vector quadword Load instruction for which the effective address (EA) is quadword-aligned places the byte in storage addressed by EA into byte element 0 of the target Vector Register, the byte in storage addressed by EA+1 into byte element 1 of the target Vector Register, etc. Similarly, a vector quadword Store instruction for which the EA is quadword-aligned places the contents of byte element 0 of the source Vector Register into the byte in storage addressed by EA, the contents of byte element 1 of the source Vector Register into the byte in storage addressed by EA+1, etc.
Figure 66 shows an aligned quadword in storage. Figure 67 shows the result of loading that quadword into a Vector Register, or, equivalently, shows the contents that must be in a Vector Register if storing that Vector Register is to produce the storage contents shown in Figure 66.

When an aligned byte, halfword, or word storage operand is loaded into a Vector Register, the element (byte, halfword, or word respectively) that receives the data is the element that would have received the data had the entire aligned quadword containing the storage operand addressed by EA been loaded. Similarly, when a byte, halfword, or word element in a Vector Register is stored into an aligned storage operand (byte, halfword, or word respectively), the element selected to be stored is the element that would have been stored into the storage operand addressed by EA had the entire Vector Register been stored to the aligned quadword containing the storage operand addressed by EA. (Byte storage operands are always aligned.)

For aligned byte, halfword, and word storage operands, if the corresponding element number is known when the program is written, the appropriate Vector Splat and Vector Permute instructions can be used to copy or replicate the data contained in the storage operand after loading the operand into a Vector Register. An example of this is given in the Programming Note for Vector Splat; see page 196. Another example is to replicate the element across an entire Vector Register before storing it into an arbitrary aligned storage operand of the same length; the replication ensures that the correct data are stored regardless of the offset of the storage operand in its aligned quadword in storage.
5.4.1 Accessing Unaligned Storage Operands

Figure 68 shows an unaligned quadword storage operand that spans two aligned quadwords. In the remainder of this section, the aligned quadword that contains the most significant bytes of the unaligned quadword is called the most significant quadword (MSQ) and the aligned quadword that contains the least significant bytes of the unaligned quadword is called the least significant quadword (LSQ). Because the Vector Storage Access instructions ignore the low-order bits of the effective address, the unaligned quadword cannot be transferred between storage and a Vector Register using a single instruction. The remainder of this section gives examples of accessing unaligned quadword storage operands. Similar sequences can be used to access unaligned halfword and word storage operands.

Programming Note

The sequence of instructions given below is one approach that can be used to load the unaligned quadword shown in Figure 68 into a Vector Register. In Figure 69 Vhi and Vlo are the Vector Registers that will receive the most significant quadword and least significant quadword respectively. VRT is the target Vector Register.

After the two quadwords have been loaded into Vhi and Vlo, using Load Vector Indexed instructions, the alignment is performed by shifting the 32-byte quantity Vhi || Vlo left by an amount determined by the address of the first byte of the desired data. The shifting is done using a Vector Permute instruction for which the permute control vector is generated by a Load Vector for Shift Left instruction. The Load Vector for Shift Left instruction uses the same address specification as the Load Vector Indexed instruction that loads the Vhi register; this is the address of the desired unaligned quadword.

The following sequence of instructions copies the unaligned quadword storage operand into register Vt.

```
# Assumptions:
# Rb != 0 and contents of Rb = 0xB
lvx    Vhi,0,Rb      # load MSQ
lvx    Vlo,0,Rb      # load LSQ
lvsl   Vp,0,Rb       # set permute control vector
addi   Rb,Rb,16      # address of LSQ
lvx    Vlo,0,Rb      # load LSQ
vperm  Vt,Vhi,Vlo,Vp # align the data
```

The procedure for storing an unaligned quadword is essentially the reverse of the procedure for loading one. However, a read-modify-write sequence is required that inserts the source quadword into two aligned quadwords in storage. The quadword to be stored is assumed to be in Vs; see Figure 69. The contents of Vs are shifted right and split into two parts, each of which is merged (using a Vector Select instruction) with the current contents of the two aligned quadwords (MSQ and LSQ) that will contain the most significant bytes and least significant bytes, respectively, of the unaligned quadword. The resulting two quadwords are stored using Store Vector Indexed instructions. A Load Vector for Shift Right instruction is used to generate the permute control vector that is used for the shifting. A single register is used for the “shifted” contents; this is possible because the “shifting” is done by means of a right rotation. The rotation is accomplished by specifying Vs for both components of the Vector Permute instruction. In addition, the same permute control vector is used on a sequence of 1s and 0s to generate the mask used by the Vector Select instructions that do the merging.

The following sequence of instructions copies the contents of Vs into an unaligned quadword in storage.

```
# Assumptions:
# Rb := 0 and contents of Rb = 0xB
lvx    Vhi,0,Rb      # load current MSQ
lvx    Vlo,0,Rb      # load current LSQ
lvsr   Vp,0,Rb       # set permute control vector
addi   Rb,Rb,16      # address of LSQ
vperm  Vmask,V0s,V1s,Vp # generate the select mask
vperm  Vs,Vs,Vs,Vp    # right rotate the data
vsel   Vlo,Vs,Vlo,Vmask # insert LSQ component
vsel   Vhi,Vhi,Vso,Vmask # insert MSQ component
stvx   Vlo,0,Rb      # store LSQ
addi   Rb,Rb,-16     # address of MSQ
stvx   Vhi,0,Rb      # store MSQ
```
5.5 Vector Integer Operations

Many of the instructions that produce fixed-point integer results have the potential to compute a result value that cannot be represented in the target format. When this occurs, this unrepresentable intermediate value is converted to a representable result value using one of the following methods.

1. The high-order bits of the intermediate result that do not fit in the target format are discarded. This method is used by instructions having names that include the word "Modulo".

2. The intermediate result is converted to the nearest value that is representable in the target format (i.e., to the minimum or maximum representable value, as appropriate). This method is used by instructions having names that include the word "Saturate". An intermediate result that is forced to the minimum or maximum representable value as just described is said to "saturate".

An instruction for which an intermediate result saturates causes VSCR\textsubscript{SAT} to be set to 1; see Section 5.3.2.

3. If the intermediate result includes non-zero fraction bits it is rounded up to the nearest fixed-point integer value. This method is used by the six Vector Average Integer instructions and by the Vector Multiply-High-Round-Add Signed Halfword Saturate instruction. The latter instruction then uses method 2, if necessary.

Programming Note

Because VSCR\textsubscript{SAT} is sticky, it can be used to detect whether any instruction in a sequence of “Saturate”-type instructions produced an inexact result due to saturation. For example, the contents of the VSCR can be copied to a VR (mfvscr), bits other than the SAT bit can be cleared in the VR (vand with a constant), the result can be compared to zero setting CR6 (vcmpequb), and a branch can be taken according to whether VSCR\textsubscript{SAT} was set to 1 (Branch Conditional that tests CR field 6).

Testing VSCR\textsubscript{SAT} after each “Saturate”-type instruction would degrade performance considerably. Alternative techniques include the following:

- Retain sufficient information at "checkpoints" that the sequence of computations performed between one checkpoint and the next can be redone (more slowly) in a manner that detects exactly when saturation occurs. Test VSCR\textsubscript{SAT} only at checkpoints, or when redoing a sequence of computations that saturated.

- Perform intermediate computations using an element length sufficient to prevent saturation, and then use a Vector Pack Integer Saturate instruction to pack the final result to the desired length. (Vector Pack Integer Saturate causes results to saturate if necessary, and sets VSCR\textsubscript{SAT} to 1 if any result saturates.)

5.5.1 Integer Saturation

Saturation occurs whenever the result of a saturating instruction does not fit in the result field. Unsigned saturation clamps results to zero (0) on underflow and to the maximum positive integer value ($2^{n-1}$, e.g. 255 for byte fields) on overflow. Signed saturation clamps results to the smallest representable negative number ($-2^{n-1}$, e.g. -128 for byte fields) on underflow, and to the largest representable positive number ($2^{n-1}$-1, e.g. +127 for byte fields) on overflow.
In most cases, the simple maximum/minimum saturation performed by the vector instructions is adequate. However, sometimes, e.g. in the creation of very high quality images, more complex saturation functions must be applied. To support this, the Vector facility provides a mechanism for detecting that saturation has occurred. The VSCR has a bit, the SAT bit, which is set to a one (1) anytime any field in a saturating instruction saturates. The SAT bit can only be cleared by explicitly writing zero to it. Thus SAT accumulates a summary result of any integer overflow or underflow that occurs on a saturating instruction.

Borderline cases that generate results equal to saturation values, for example unsigned 0+0=0 and unsigned byte 1+254=255, are not considered saturation conditions and do not cause SAT to be set.

The SAT bit can be set by the following types of instructions:

- Move To VSCR
- Vector Add Integer with Saturation
- Vector Subtract Integer with Saturation
- Vector Multiply-Add Integer with Saturation
- Vector Multiply-Sum with Saturation
- Vector Sum-Across with Saturation
- Vector Pack with Saturation
- Vector Convert to Fixed-point with Saturation

Note that only instructions that explicitly call for “saturation” can set SAT. “Modulo” integer instructions and floating-point arithmetic instructions never set SAT.

---

**Programming Note**

The SAT state can be tested and used to alter program flow by moving the VSCR to a vector register (with `mfvscr`), then masking out bits 0:126 (to clear undefined and reserved bits) and performing a vector compare equal-to unsigned byte w/record (`vcmpequb`) with zero to get a testable value into the condition register for consumption by a subsequent branch.

Since `mfvscr` will be slow compared to other Vector instructions, reading and testing SAT after each instruction would be prohibitively expensive. Therefore, software is advised to employ strategies that minimize checking SAT. For example: checking SAT periodically and backtracking to the last checkpoint to identify exactly which field in which instruction saturated; or, working in an element size sufficient to prevent any overflow or underflow during intermediate calculations, then packing down to the desired element size as the final operation (the vector pack instruction saturates the results and updates SAT when a loss of significance is detected).
5.6 Vector Floating-Point Operations

5.6.1 Floating-Point Overview

Unless VSCR_{NJ}=1 (see Section 5.3.2), the floating-point model provided by the Vector Facility conforms to The Java Language Specification (hereafter referred to as "Java"), which is a subset of the default environment specified by the IEEE standard (i.e., by ANSI/IEEE Standard 754-1985, "IEEE Standard for Binary Floating-Point Arithmetic"). For aspects of floating-point behavior that are not defined by Java but are defined by the IEEE standard, vector floating-point conforms to the IEEE standard. For aspects of floating-point behavior that are defined neither by Java nor by the IEEE standard but are defined by the "C9X Floating-Point Proposal" (hereafter referred to as "C9X"), vector floating-point conforms to C9X.

The single-precision floating-point data format, value representations, and computational models defined in Chapter 4. "Floating-Point Facility [Category: Floating-Point]" on page 115 apply to vector floating-point except as follows.

- In general, no status bits are set to reflect the results of floating-point operations. The only exception is that VSCR_{SAT} may be set by the Vector Convert To Fixed-Point Word instructions.

- With the exception of the two Vector Convert To Fixed-Point Word instructions and three of the four Vector Round To Floating-Point Integer instructions, all vector floating-point instructions that round use the rounding mode Round to Nearest.

- Floating-point exceptions (see Section 5.6.2) cannot cause the system error handler to be invoked.

Programming Note

If a function is required that is specified by the IEEE standard, is not supported by the Vector Facility, and cannot be emulated satisfactorily using the functions that are supported by the Vector Facility, the functions provided by the Floating-Point Facility should be used; see Chapter 4.

5.6.2 Floating-Point Exceptions

The following floating-point exceptions may occur during execution of vector floating-point instructions.

- NaN Operand Exception
- Invalid Operation Exception
- Zero Divide Exception
- Log of Zero Exception
- Overflow Exception
- Underflow Exception

If an exception occurs, a result is placed into the corresponding target element as described in the following subsections. This result is the default result specified by Java, the IEEE standard, or C9X, as applicable.

Recall that denormalized source values are treated as if they were zero when VSCR_{NJ}=1. This has the following consequences regarding exceptions.

- Exceptions that can be caused by a zero source value can be caused by a denormalized source value when VSCR_{NJ}=1.

- Exceptions that can be caused by a nonzero source value cannot be caused by a denormalized source value when VSCR_{NJ}=1.

5.6.2.1 NaN Operand Exception

A NaN Operand Exception occurs when a source value for any of the following instructions is a NaN.

- A vector instruction that would normally produce floating-point results
- Either of the two Vector Convert To Fixed-Point Word instructions
- Any of the four Vector Floating-Point Compare instructions

The following actions are taken:

If the vector instruction would normally produce floating-point results, the corresponding result is a source NaN selected as follows. In all cases, if the selected source NaN is a Signaling NaN it is converted to the corresponding Quiet NaN (by setting the high-order bit of the fraction field to 1) before being placed into the target element.

if the element in VRA is a NaN then the result is that NaN
else if the element in VRB is a NaN then the result is that NaN
else if the element in VRC is a NaN

if a function is required that is specified by the IEEE standard, is not supported by the Vector Facility, and cannot be emulated satisfactorily using the functions that are supported by the Vector Facility, the functions provided by the Floating-Point Facility should be used; see Chapter 4.
then the result is that NaN
else if Invalid Operation exception
    (Section 5.6.2.2)
then the result is the QNaN 0x7FC0_0000

If the instruction is either of the two Vector Convert To Fixed-Point Word instructions, the corresponding result is 0x0000_0000. VSCR\textsubscript{SAT} is not affected.

If the instruction is Vector Compare Bounds Floating-Point, the corresponding result is 0xC000_0000.

If the instruction is one of the other Vector Floating-Point Compare instructions, the corresponding result is 0x0000_0000.

### 5.6.2.2 Invalid Operation Exception

An Invalid Operation Exception occurs when a source value or set of source values is invalid for the specified operation. The invalid operations are:

- Magnitude subtraction of infinities
- Multiplication of infinity by zero
- Reciprocal square root estimate of a negative, nonzero number or -infinity.
- Log base 2 estimate of a negative, nonzero number or -infinity.

The corresponding result is the QNaN 0x7FC0_0000.

### 5.6.2.3 Zero Divide Exception

A Zero Divide Exception occurs when a Vector Reciprocal Estimate Floating-Point or Vector Reciprocal Square Root Estimate Floating-Point instruction is executed with a source value of zero.

The corresponding result is an infinity, where the sign is the sign of the source value.

### 5.6.2.4 Log of Zero Exception

A Log of Zero Exception occurs when a Vector Log Base 2 Estimate Floating-Point instruction is executed with a source value of zero.

The corresponding result is -Infinity.

### 5.6.2.5 Overflow Exception

An Overflow Exception occurs under either of the following conditions.

- For a vector instruction that would normally produce floating-point results, the magnitude of what would have been the result if the exponent range were unbounded exceeds that of the largest finite floating-point number for the target floating-point format.
- For either of the two Vector Convert To Fixed-Point Word instructions, either a source value is an infinity or the product of a source value and \(2^{\text{UM}}\) is a number too large in magnitude to be represented in the target fixed-point format.

The following actions are taken:

1. If the vector instruction would normally produce floating-point results, the corresponding result is an infinity, where the sign is the sign of the intermediate result.
2. If the instruction is Vector Convert To Unsigned Fixed-Point Word Saturate, the corresponding result is 0xFFFF_FFFF if the source value is a positive number or +infinity, and is 0x0000_0000 if the source value is a negative number or -infinity. VSCR\textsubscript{SAT} is set to 1.
3. If the instruction is Vector Convert To Signed Fixed-Point Word Saturate, the corresponding result is 0x7FFF_FFFF if the source value is a positive number or +infinity, and is 0x8000_0000 if the source value is a negative number or -infinity. VSCR\textsubscript{SAT} is set to 1.

### 5.6.2.6 Underflow Exception

An Underflow Exception can occur only for vector instructions that would normally produce floating-point results. It is detected before rounding. It occurs when a nonzero intermediate result computed as though both the precision and the exponent range were unbounded is less in magnitude than the smallest normalized floating-point number for the target floating-point format.

The following actions are taken:

1. If VSCR\textsubscript{NJ}=0, the corresponding result is the value produced by denormalizing and rounding the intermediate result.
2. If VSCR\textsubscript{NJ}=1, the corresponding result is a zero, where the sign is the sign of the intermediate result.
5.7 Vector Storage Access Instructions

The Storage Access instructions compute the effective address (EA) of the storage to be accessed as described in Section 1.10.3, “Effective Address Calculation” on page 26. The low-order bits of the EA that would correspond to an unaligned storage operand are ignored.

The Load Vector Element Indexed and Store Vector Element Indexed instructions transfer a byte, halfword, or word element between storage and a Vector Register. The Load Vector Indexed and Store Vector Indexed instructions transfer an aligned quadword between storage and a Vector Register.

5.7.1 Storage Access Exceptions

Storage accesses will cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (Store only), or if the program attempts to access storage that is unavailable.
5.7.2 Vector Load Instructions

The aligned byte, halfword, word, or quadword in storage addressed by EA is loaded into register VRT.

**Load Vector Element Byte Indexed X-form**

\[ \text{lvebx VRT,RA,RB} \]

<table>
<thead>
<tr>
<th>31</th>
<th>VRT</th>
<th>RA</th>
<th>RB</th>
<th>7</th>
</tr>
</thead>
</table>

if RA = 0 then b ← 0
else b ← (RA)
EA ← b + (RB)
eb ← EA60:63
VRT ← undefined
if Big-Endian byte ordering then
VRT8×eb:8×eb+7 ← MEM(EA,1)
else
VRT120-(8×eb):127-(8×eb) ← MEM(EA,1)

Let the effective address (EA) be the sum (RA|0)+(RB).

Let eb be bits 60:63 of EA.

If Big-Endian byte ordering is used for the storage access, the contents of the byte in storage at address EA are placed into byte eb of register VRT. The remaining bytes in register VRT are set to undefined values.

If Category: Vector.Little-Endian is supported, then if Little-Endian byte ordering is used for the storage access, the contents of the byte in storage at address EA are placed into byte 15-eb of register VRT. The remaining bytes in register VRT are set to undefined values.

**Special Registers Altered:**

None

**Load Vector Element Halfword Indexed X-form**

\[ \text{lvehx VRT,RA,RB} \]

<table>
<thead>
<tr>
<th>31</th>
<th>VRT</th>
<th>RA</th>
<th>RB</th>
<th>39</th>
</tr>
</thead>
</table>

if RA = 0 then b ← 0
else b ← (RA)
EA ← (b + (RB)) & 0xFFFF_FFFF_FFFF_FFFE

- \( \text{mark}_{\text{as_not Likely_to_be_needed}_again(_anytime_soon)}(\text{EA}) \)

Let the effective address (EA) be the sum \((\text{RA}(0)+(\text{RB}))\). The quadword in storage addressed by the result of EA ANDed with \( 0xFFFF_FFFF_FFFF_FFF0 \) is loaded into VRT.

\( \text{lvxl} \) provides a hint that the quadword in storage addressed by EA will probably not be needed again by the program in the near future.

**Special Registers Altered:**

None
On some implementations, the hint provided by the \texttt{lvxl} instruction and the corresponding hint provided by the \texttt{stvxl}, \texttt{lvepxl}, and \texttt{stvepxl} instructions are applied to the entire cache block containing the specified quadword. On such implementations, the effect of the hint may be to cause that cache block to be considered a likely candidate for replacement when space is needed in the cache for a new block. Thus, on such implementations, the hint should be used with caution if the cache block containing the quadword also contains data that may be needed by the program in the near future. Also, the hint may be used before the last reference in a sequence of references to the quadword if the subsequent references are likely to occur sufficiently soon that the cache block containing the quadword is not likely to be displaced from the cache before the last reference.

---

**Programming Note**

On some implementations, the hint provided by the \texttt{lvxl} instruction and the corresponding hint provided by the \texttt{stvxl}, \texttt{lvepxl}, and \texttt{stvepxl} instructions are applied to the entire cache block containing the specified quadword. On such implementations, the effect of the hint may be to cause that cache block to be considered a likely candidate for replacement when space is needed in the cache for a new block. Thus, on such implementations, the hint should be used with caution if the cache block containing the quadword also contains data that may be needed by the program in the near future. Also, the hint may be used before the last reference in a sequence of references to the quadword if the subsequent references are likely to occur sufficiently soon that the cache block containing the quadword is not likely to be displaced from the cache before the last reference.
5.7.3 Vector Store Instructions

Some portion or all of the contents of VRS are stored into the aligned byte, halfword, word, or quadword in storage addressed by EA.

--- Programming Note ---

The Store Vector Element instructions store the specified element into the same storage location as the location into which it would be stored using the Store Vector instruction.

--- Store Vector Element Byte Indexed X-form ---

\[ \text{stvebx} \quad \text{VRS},\text{RA},\text{RB} \]

<table>

---

Programming Note

Examples of uses of **lvsl**, **lvsr**, and **vperm** to load and store unaligned data are given in Section 5.4.1.

These instructions can also be used to rotate or shift the contents of a Vector Register left (**lvsl**) or right (**lvsr**) by sh bytes. For rotating, the Vector Register to be rotated should be specified as both register VRA and VRB for **vperm**. For shifting left, VRB for **vperm** should be a register containing all zeros and VRA should contain the value to be shifted, and vice versa for shifting right.

---

5.8 Vector Permute and Formatting Instructions

5.8.1 Vector Pack and Unpack Instructions

**Vector Pack Pixel VX-form**

```
vpkpx VRT, VRA, VRB
```

<table>
<thead>
<tr>
<th></th>
<th>VRT</th>
<th>VRA</th>
<th>VRB</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td></td>
<td></td>
<td></td>
<td>782</td>
</tr>
</tbody>
</table>

Let the source vector be the concatenation of the contents of `VR[VRA]` followed by the contents of `VR[VRB]`.

For each integer value `i` from 0 to 7, do the following.

Word element `i` in the source vector is packed to produce a 16-bit value as described below.

- bit 7 of the first byte (bit 7 of the word)
- bits 0:4 of the second byte (bits 8:12 of the word)
- bits 0:4 of the third byte (bits 16:20 of the word)
- bits 0:4 of the fourth byte (bits 24:28 of the word)

The result is placed into halfword element `i` of `VR[VRT].`

**Special Registers Altered:**

None

**Programming Note**

Each source word can be considered to be a 32-bit "pixel", consisting of four 8-bit "channels". Each target halfword can be considered to be a 16-bit pixel, consisting of one 1-bit channel and three 5-bit channels. A channel can be used to specify the intensity of a particular color, such as red, green, or blue, or to provide other information needed by the application.

**Vector Pack Signed Doubleword Signed Saturate VX-form**

```
vpksdss VRT, VRA, VRB
```

<table>
<thead>
<tr>
<th></th>
<th>VRT</th>
<th>VRA</th>
<th>VRB</th>

<td></td>
<td></td>
<td>1486</td>
</tr>
</tbody>
</table>

Let doubleword elements 0 and 1 of `src` be the contents of `VR[VRA].`

Let doubleword elements 2 and 3 of `src` be the contents of `VR[VRB].`

For each integer value `i` from 0 to 3, do the following.

The signed integer value in doubleword element `i` of `src` is placed into word element `i` of `VR[VRT]` in signed integer format.

- If the value is greater than 2^31-1 the result saturates to 2^31-1.
- If the value is less than -2^31 the result saturates to -2^31.

**Special Registers Altered:**

`SAT`

\end{align*}
\]
end

For each vector element \( i \) from 0 to 3, do the following.
Halfword element \( i+4 \) in VRB is unpacked as follows.

- sign-extend bit 0 of the halfword to 8 bits
- zero-extend bits 1:5 of the halfword to 8 bits
- zero-extend bits 6:10 of the halfword to 8 bits
- zero-extend bits 11:15 of the halfword to 8 bits

The result is placed in word element \( i \) of VRT.

Special Registers Altered:
None

Programming Note

Notice that the unpacking done by the Vector Unpack Pixel instructions does not reverse the packing done by the Vector Pack Pixel instruction. Specifically, if a 16-bit pixel is unpacked to a 32-bit pixel which is then packed to a 16-bit pixel, the resulting 16-bit pixel will not, in general, be equal to the original 16-bit pixel (because, for each channel except the first, Vector Unpack Pixel inserts high-order bits while Vector Pack Pixel discards low-order bits).

5.8.3 Vector Splat Instructions

**Programming Note**
The Vector Splat instructions can be used in preparation for performing arithmetic for which one source vector is to consist of elements that all have the same value (e.g., multiplying all elements of a Vector Register by a constant).

### Vector Splat Byte VX-form

#### vspltb

\[ \text{VRT}, \text{VRB}, \text{UIM} \]

\[
\begin{array}{c|c|c|c|c}
\hline
4 & 6 & 11 & 16 & 21 \\
\hline
\end{array}
\]

\[
\text{b} \leftarrow \text{UIM} \| 0b0000 \\text{do i=0 to 127 by 8} \\text{VRT}_{i:i+7} \leftarrow (\text{VRB})_{b:b+7} \\text{end}
\]

For each integer value \( i \) from 0 to 15, do the following. The contents of byte element UIM in VRB are placed into byte element \( i \) of VRT.

**Special Registers Altered:**

None

### Vector Splat Halfword VX-form

#### vsplth

\[ \text{VRT}, \text{VRB}, \text{UIM} \]

\[
\begin{array}{c|c|c|c|c}
\hline
4 & 6 & 11 & 16 & 21 \\
\hline
\end{array}
\]

\[
\text{b} \leftarrow \text{UIM} \| 0b00000 \\text{do i=0 to 127 by 16} \\text{VRT}_{i:i+15} \leftarrow (\text{VRB})_{b:b+15} \\text{end}
\]

For each integer value \( i \) from 0 to 15, do the following. The contents of halfword element UIM in VRB are placed into halfword element \( i \) of VRT.

**Special Registers Altered:**

None

### Vector Splat Word VX-form

#### vspltw

\[ \text{VRT}, \text{VRB}, \text{UIM} \]

\[
\begin{array}{c|c|c|c|c}
\hline
4 & 6 & 11 & 16 & 21 \\
\hline
\end{array}
\]

\[
\text{b} \leftarrow \text{UIM} \| 0b00000 \\text{do i=0 to 127 by 32} \\text{VRT}_{i:i+31} \leftarrow (\text{VRB})_{b:b+31} \\text{end}
\]

For each integer value \( i \) from 0 to 3, do the following. The contents of word element UIM in VRB are placed into word element \( i \) of VRT.

**Special Registers Altered:**

None
### Vector Splat Immediate Signed Byte VX-form

<table>
<thead>
<tr>
<th>V</th>
<th>4</th>
<th>VRT</th>

<th>///</th>
<th>780</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>31</td>
</tr>
</tbody>
</table>

For each integer value \(i\) from 0 to 15, do the following.
The value of the SIM field, sign-extended to 8 bits, is placed into byte element \(i\) of VRT.

**Special Registers Altered:**
None

### Vector Splat Immediate Signed Halfword VX-form

<table>
<thead>
<tr>
<th>V</th>
<th>4</th>
<th>VRT</th>
<th>SIM</th>
<th>///</th>
<th>844</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>31</td>
</tr>
</tbody>
</table>

For each integer value \(i\) from 0 to 7, do the following.
The value of the SIM field, sign-extended to 16 bits, is placed into halfword element \(i\) of VRT.

**Special Registers Altered:**
None

### Vector Splat Immediate Signed Word VX-form

<table>
<thead>
<tr>
<th>V</th>
<th>4</th>
<th>VRT</th>
<th>SIM</th>
<th>///</th>
<th>908</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>31</td>
</tr>
</tbody>
</table>

For each vector element \(i\) from 0 to 3, do the following.
The value of the SIM field, sign-extended to 32 bits, is placed into word element \(i\) of VRT.

**Special Registers Altered:**
None

### 5.8.4 Vector Permute Instruction

The **Vector Permute** instruction allows any byte in two source Vector Registers to be copied to any byte in the target Vector Register. The bytes in a third source Vector Register specify from which byte in the first two source Vector Registers the corresponding target byte is to be copied. The contents of the third source Vector Register are sometimes referred to as the “permute control vector”.

#### Vector Permute VA-form

<table>
<thead>
<tr>
<th>V</th>
<th>4</th>
<th>VRT, VRA, VRB, VRC</th>
<th>26</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>///</td>
<td>43</td>
</tr>
</tbody>
</table>

Let the source vector be the concatenation of the contents of VRA followed by the contents of VRB.

For each integer value \(i\) from 0 to 15, do the following.
The contents of the byte element in the source vector specified by bits 3:7 of byte element \(i\) of VRC are placed into byte element \(i\) of VRT.

**Special Registers Altered:**
None

**Programming Note**

See the Programming Notes with the **Load Vector for Shift Left** and **Load Vector for Shift Right** instructions on page 186 for examples of uses of vperm.
5.8.5 Vector Select Instruction

**Vector Select VA-form**

```
vsel VRT,VRA,VRB,VRC
```

<table>
<thead>
<tr>
<th></th>
<th>VRT</th>
<th>VRA</th>
<th>VRB</th>
<th>VRC</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
<tr>
<td>0</td>
<td>26</td>
<td>31</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

\[\text{do } i=0 \text{ to 127}\]

\[\text{VRT}_i \leftarrow (\text{VRC}_i=0) \ ? \ (\text{VRA})_i : (\text{VRB})_i\]

For each bit in VRC that contains the value 0, the corresponding bit in VRA is placed into the corresponding bit of VRT. Otherwise, the corresponding bit in VRB is placed into the corresponding bit of VRT.

**Special Registers Altered:**

None
5.8.6 Vector Shift Instructions

The Vector Shift instructions rotate or shift the contents of a Vector Register or a pair of Vector Registers left or right by a specified number of bytes (vslo, vsro, vsldoi) or bits (vsl, vsr). Depending on the instruction, this “shift count” is specified either by the contents of a Vector Register or by an immediate field in the instruction. In the former case, 7 bits of the shift count register give the shift count in bits (0 ≤ count ≤ 127). Of these 7 bits, the high-order 4 bits give the number of complete bytes by which to shift and are used by vslo and vsro; the low-order 3 bits give the number of remaining bits by which to shift and are used by vsl and vsr.

### Vector Shift Left VX-form

**vsl**

<table>
<thead>
<tr>
<th>4</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>452</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>452</td>
</tr>
</tbody>
</table>

\[ sh \leftarrow (\text{VRB})_{125:127} \]
\[ t \leftarrow 1 \]
\[ \text{do } i=0 \text{ to } 127 \text{ by } 8 \]
\[ t \leftarrow t \& ((\text{VRB})_{i:7}=sh) \]
\[ \text{if } t=1 \text{ then } \text{VRT} \leftarrow (\text{VRA}) \ll sh \]
\[ \text{else } \text{VRT} \leftarrow \text{undefined} \]

The contents of VRA are shifted left by the number of bits specified in (VRB)_125:127.

- Bits shifted out of bit 0 are lost.
- Zeros are supplied to the vacated bits on the right.

The result is placed into VRT, except if, for any byte element in register VRB, the low-order 3 bits are not equal to the shift amount, then VRT is undefined.

**Special Registers Altered:**

None

### Vector Shift Left Double by Octet Immediate VA-form

**vsldoi**

<table>
<thead>
<tr>
<th>4</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>44</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>44</td>
</tr>
</tbody>
</table>

\[ \text{VRT} \leftarrow (\text{VRA})_0 \mid (\text{VRB})_8:8+127 \]

Let the source vector be the concatenation of the contents of VRA followed by the contents of VRB. Bytes SHB:SHB+15 of the source vector are placed into VRT.

**Special Registers Altered:**

None

### Vector Shift Left by Octet VX-form

**vslo**

<table>
<thead>
<tr>
<th>4</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>1036</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>1036</td>
</tr>
</tbody>
</table>

\[ shb \leftarrow (\text{VRB})_{121:124} \]
\[ \text{VRT} \leftarrow (\text{VRA}) \ll (shb \mid 0b000) \]

The contents of VRA are shifted left by the number of bytes specified in (VRB)_121:124.

- Bytes shifted out of byte 0 are lost.
- Zeros are supplied to the vacated bytes on the right.

The result is placed into VRT.

**Special Registers Altered:**

None
Vector Shift Right VX-form

vrsh VRT, VRA, VRB

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
 & VRT & VRA & VRB & 708 \\
\hline
 0 & 4 & 6 & 11 & 16 & 21 & 31 \\
\hline
\end{array}
\]

\[
sh \leftarrow (\text{VRB})_{125:127}
\]
\[
t \leftarrow 1
\]
do i=0 to 127 by 8
\[
t \leftarrow t \& (\text{VRB})_{15,16}=sh
\]
end
if t=1 then VRT \leftarrow (VRA) >>ui sh
else VRT undefined

The contents of VRA are shifted right by the number of bits specified in (VRB)_{125:127}.

- Bits shifted out of bit 127 are lost.
- Zeros are supplied to the vacated bits on the left.

The result is placed into VRT, except if, for any byte element in register VRB, the low-order 3 bits are not equal to the shift amount, then VRT is undefined.

Special Registers Altered:
None

Programming Note

A double-register shift by a dynamically specified number of bits (0-127) can be performed in six instructions. The following example shifts Vw || Vx left by the number of bits specified in Vy and places the high-order 128 bits of the result into Vz.

\[
\begin{align*}
\text{vslo} & \quad \text{Vt1.Vw.Vy} \quad \#\text{shift high-order reg left} \\
\text{vsl} & \quad \text{Vt1.Vt1.Vy} \\
\text{vsabkh} & \quad \text{Vt3.V0.Vy} \quad \#\text{adjust shift count (V0)=0} \\
\text{vsro} & \quad \text{Vt2.Vx.Vz} \quad \#\text{shift low-order reg right} \\
\text{vsr} & \quad \text{Vt2.Vt2.Vz} \\
\text{vor} & \quad \text{Vz.Vt1.Vt3} \quad \#\text{merge to get final result}
\end{align*}
\]

Vector Shift Right by Octet VX-form

vsro VRT, VRA, VRB

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
 & VRT & VRA & VRB & 1100 \\
\hline
 0 & 4 & 6 & 11 & 16 & 21 & 31 \\
\hline
\end{array}
\]

\[
shb \leftarrow (\text{VRB})_{121:124}
\]
\[
\text{VRT} \leftarrow (\text{VRA}) >>ui (shb \| 0b000)
\]

The contents of VRA are shifted right by the number of bytes specified in (VRB)_{121:124}.

- Bytes shifted out of byte 15 are lost.
- Zeros are supplied to the vacated bytes on the left.

The result is placed into VRT.

Special Registers Altered:

</table>

For each integer value i from 0 to 3, do the following.

Unsigned-integer word element i in VRA is added to unsigned-integer word element i in VRB.

- If the sum is greater than $2^{32} - 1$, the result saturates to $2^{32} - 1$.

The low-order 32 bits of the result are placed into word element i of VRT.

<th>VRA</th>
<th>VRB</th>
<th>1408</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>31</td>
</tr>
</tbody>
</table>

do i=0 to 127 by 32
    aop ← EXTZ((VRA)[i:i+31])
    bop ← EXTZ((VRB)[i:i+31])
    temp ← (aop + int ¬bop + int 1) >> 32
    VRT[i:i+31] ← temp & 0x0000_0001
end
```

For each integer value i from 0 to 3, do the following.
Unsigned-integer word element i in VRB is subtracted from unsigned-integer word element i in VRA. The complement of the borrow out of bit 0 of the 32-bit difference is zero-extended to 32 bits and placed into word element i of VRT.

**Special Registers Altered:**  
None

---

**Vector Subtract Signed Halfword Saturate**  
*VX-form*

```
vsubshs VRT,VRA,VRB
```

<table>
<thead>
<tr>

The sum of signed-integer word elements 2 and 3 in **VRA** is added to the signed-integer word element in bits 96:127 of **VRB**.

- If the intermediate result is greater than 2^31-1 the result saturates to 2^31-1.
- If the intermediate result is less than -2^31 the result saturates to -2^31.

The low-order 32 bits of the result are placed into word element 3 of **VRT**.

**Special Registers Altered:**

SAT
**Vector Sum across Quarter Signed Byte Saturate VX-form**

\[
vsum4sbs\begin{array}{c|c|c|c|c}
\text{VRT} & \text{VRA} & \text{VRB} & \text{1800} \\
4 & 6 & 31 & 21 & 31 \\
\end{array}
\]

\begin{verbatim}
do i=0 to 127 by 32
    temp ← EXTS((VRB)_{i:i+31})
do j=0 to 31 by 8
    temp ← temp + int EXTS((VRA)_{i+j:i+j+7})
end
VRT_{i:i+31} ← Clamp(temp, -2^{31}, 2^{31}-1)
end
\end{verbatim}

For each integer value \( i \) from 0 to 3, do the following.

The sum of the four signed-integer byte elements contained in word element \( i \) of VRA is added to signed-integer word element \( i \) in VRB.

- If the intermediate result is greater than \( 2^{31}-1 \) the result saturates to \( 2^{31}-1 \).
- If the intermediate result is less than \( -2^{31} \) the result saturates to \( -2^{31} \).

The low-order 32 bits of the result are placed into word element \( i \) of VRT.

Special Registers Altered:

5.9.2 Vector Integer Compare Instructions

The **Vector Integer Compare** instructions compare two Vector Registers element by element, interpreting the elements as unsigned or signed-integers depending on the instruction, and set the corresponding element of the target Vector Register to all 1s if the relation being tested is true and to all 0s if the relation being tested is false.

If \( Rc=1 \) CR Field 6 is set to reflect the result of the comparison, as follows.

**Vector Compare Equal To Unsigned Byte VC-form**

<table>
<thead>
<tr>
<th>Vcmpequb</th>
<th>VRT, VRA, VRB ( (Rc=0) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vcmpequb.</td>
<td>VRT, VRA, VRB ( (Rc=1) )</td>
</tr>
</tbody>
</table>

For each integer value \( i \) from 0 to 15, do the following.

Unsigned-integer byte element \( i \) in VRA is compared to unsigned-integer byte element \( i \) in VRB. Byte element \( i \) in VRT is set to all 1s if unsigned-integer byte element \( i \) in VRA is equal to unsigned-integer byte element \( i \) in VRB, and is set to all 0s otherwise.

**Special Registers Altered:**

\( CR \) field \( 6 \) .......................... \( (if \ Rc=1) \)

**Vector Compare Equal To Unsigned Halfword VC-form**

<table>
<thead>
<tr>
<th>Vcmpequh</th>

5.9.3 Vector Logical Instructions

Extended mnemonics for vector logical operations

Extended mnemonics are provided that use the Vector OR and Vector NOR instructions to copy the contents of one Vector Register to another, with and without complementing. These are shown as examples with the two instructions.

**Vector Move Register**

Several vector instructions can be coded in a way such that they simply copy the contents of one Vector Register to another. An extended mnemonic is provided to convey the idea that no computation is being performed but merely data movement (from one register to another).

The following instruction copies the contents of register \( V_y \) to register \( V_x \).

\[ \text{vmr } V_x, V_y \quad (\text{equivalent to: } \text{vor } V_x, V_y, V_y) \]

**Vector Complement Register**

The Vector NOR instruction can be coded in a way such that it complements the contents of one Vector Register and places the result into another Vector Register. An extended mnemonic is provided that allows this operation to be coded easily.

The following instruction complements the contents of register \( V_y \) and places the result into register \( V_x \).

\[ \text{vnot } V_x, V_y \quad (\text{equivalent to: } \text{vnor } V_x, V_y, V_y) \]

**Vector Logical AND VX-form**

\[ \text{vand } V_{RT}, V_{RA}, V_{RB} \]

\[
\begin{array}{cccccc}
4 & 4 & 11 & 16 & 21 & 31 \\
0 & 6 & 6 & 6 & 6 & 6 \\
\end{array}
\]

\[ V_{RT} \leftarrow V_{RA} \land V_{RB} \]

The contents of \( V_{RA} \) are ANDed with the contents of \( V_{RB} \) and the result is placed into \( V_{RT} \).

**Special Registers Altered:** None

**Vector Logical AND with Complement VX-form**

\[ \text{vandc } V_{RT}, V_{RA}, V_{RB} \]

\[
\begin{array}{cccccc}
4 & 4 & 11 & 16 & 21 & 31 \\
0 & 6 & 6 & 6 & 6 & 6 \\
\end{array}
\]

\[ V_{RT} \leftarrow V_{RA} \land \neg V_{RB} \]

The contents of \( V_{RA} \) are ANDed with the complement of the contents of \( V_{RB} \) and the result is placed into \( V_{RT} \).

**Special Registers Altered:** None

**Vector Logical Equivalent VX-form**

\[ \text{veqv } V_{RT}, V_{RA}, V_{RB} \]

\[
\begin{array}{cccccc}

5.9.4 Vector Integer Rotate and Shift Instructions

### Vector Rotate Left Byte VX-form

- **Syntax:** `vrlb VRT, VRA, VRB`
- **Operation:**
  
  ```
  do i=0 to 127 by 8
  sh ← (VRB)i+5:i+7
  VRTi:i+7 ← (VRA)i:i+7 <<< sh
  end
  ```

  For each integer value `i` from 0 to 15, do the following.
  
  Byte element `i` in `VRA` is rotated left by the number of bits specified in the low-order 3 bits of the corresponding byte element `i` in `VRB`.

  The result is placed into byte element `i` in `VRT`.

  **Special Registers Altered:** None

### Vector Rotate Left Halfword VX-form

- **Syntax:** `vrlh VRT, VRA, VRB`
- **Operation:**
  
  ```
  do i=0 to 127 by 16
  sh ← (VRB)i+12:i+15
  VRTi:i+15 ← (VRA)i:i+15 <<< sh
  end
  ```

  For each integer value `i` from 0 to 7, do the following.
  
  Halfword element `i` in `VRA` is rotated left by the number of bits specified in the low-order 4 bits of the corresponding halfword element `i` in `VRB`.

  The result is placed into halfword element `i` in `VRT`.

  **Special Registers Altered:** None

### Vector Rotate Left Word VX-form

- **Syntax:** `vrlw VRT, VRA, VRB`
- **Operation:**
  
  ```
  do i=0 to 127 by 32
  sh ← (VRB)i+27:i+31
  VRTi:i+31 ← (VRA)i:i+31 <<< sh
  end
  ```

  For each integer value `i` from 0 to 3, do the following.
  
  Word element `i` in `VRA` is rotated left by the number of bits specified in the low-order 5 bits of the corresponding word element `i` in `VRB`.

  The result is placed into word element `i` in `VRT`.

  **Special Registers Altered:** None

### Vector Rotate Left Doubleword VX-form

- **Syntax:** `vrld VRT, VRA, VRB`
- **Operation:**
  
  ```
  do i=0 to 1
  sh ← VR[VRB].dword[i].bit[58:63]
  VR[VRT].dword[i] ← VR[VRA].dword[i] <<< sh
  end
  ```

  For each integer value `i` from 0 to 1, do the following.
  
  The contents of doubleword element `i` of `VR(VRA)` are rotated left by the number of bits specified in bits 58:63 of doubleword element `i` of `VR(VRB)`.

  The result is placed into doubleword element `i` of `VR(VRT)`.

  **Special Registers Altered:** None

Vector Shift Right Algebraic Byte VX-form
vsrab VRT,VRA,VRB

<table>
<thead>
<tr>
<th>do i = 0 to 127 by 8</th>
</tr>
</thead>
<tbody>
<tr>
<td>sh ← (VRB)i+5:i+7</td>
</tr>
<tr>
<td>VRTi:i+7 ← (VRA)i:i+7 &gt;&gt;si sh</td>
</tr>
<tr>
<td>end</td>
</tr>
</tbody>
</table>

For each integer value i from 0 to 15, do the following. Byte element i in VRA is shifted right by the number of bits specified in the low-order 3 bits of the corresponding byte element i in VRB. Bits shifted out of bit 7 of the byte element are lost. Bit 0 of the byte element is replicated to fill the vacated bits on the left. The result is placed into byte element i of VRT.

Special Registers Altered:
None

Vector Shift Right Algebraic Halfword VX-form
vsrah VRT,VRA,VRB

<table>
<thead>
<tr>
<th>do i = 0 to 127 by 16</th>
</tr>
</thead>
<tbody>
<tr>
<td>sh ← (VRB)i+12:i+15</td>
</tr>
<tr>
<td>VRTi:i+15 ← (VRA)i:i+15 &gt;&gt;si sh</td>
</tr>
<tr>
<td>end</td>
</tr>
</tbody>
</table>

For each integer value i from 0 to 7, do the following. Halfword element i in VRA is shifted right by the number of bits specified in the low-order 4 bits of the corresponding halfword element i in VRB. Bits shifted out of bit 15 of the halfword are lost. Bit 0 of the halfword is replicated to fill the vacated bits on the left. The result is placed into halfword element i of VRT.

Special Registers Altered:
None

Vector Shift Right Algebraic Word VX-form
vsraw VRT,VRA,VRB

<table>
<thead>
<tr>
<th>do i = 0 to 127 by 32</th>
</tr>
</thead>
<tbody>
<tr>
<td>sh ← (VRB)i+27:i+31</td>
</tr>
<tr>
<td>VRTi+31 ← (VRA)i:i+31 &gt;&gt;si sh</td>
</tr>
<tr>
<td>end</td>
</tr>
</tbody>
</table>

For each integer value i from 0 to 3, do the following. Word element i in VRA is shifted right by the number of bits specified in the low-order 5 bits of the corresponding word element i in VRB. Bits shifted out of bit 31 of the word are lost. Bit 0 of the word is replicated to fill the vacated bits on the left. The result is placed into word element i of VRT.

Special Registers Altered:

## 5.10 Vector Floating-Point Instruction Set

### 5.10.1 Vector Floating-Point Arithmetic Instructions

**Vector Add Single-Precision VX-form**

```plaintext
vaddfp VRT, VRA, VRB
```

For each integer value i from 0 to 3, do the following.
Single-precision floating-point element i in VRA is added to single-precision floating-point element i in VRB. The intermediate result is rounded to the nearest single-precision floating-point number and placed into word element i of VRT.

**Special Registers Altered:**
None

**Vector Subtract Single-Precision VX-form**

```plaintext
vsubfp VRT, VRA, VRB
```

For each integer value i from 0 to 3, do the following.
Single-precision floating-point element i in VRB is subtracted from single-precision floating-point element i in VRA. The intermediate result is rounded to the nearest single-precision floating-point number and placed into word element i of VRT.

**Special Registers Altered:**
None
**Vector Multiply-Add Single-Precision**

VA-form

\[
\text{vmaddfp } \quad \text{VRT, VRA, VRC, VRB}
\]

<table>
<thead>
<tr>
<th>4</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>26</th>
<th>46</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>VRT</td>
<td>VRA</td>
<td>VRB</td>
<td>VRC</td>
<td>46</td>
<td></td>
</tr>
</tbody>
</table>

do i=0 to 127 by 32
prod \leftarrow (\text{VRA}[i:i+31] \times \text{fp}(\text{VRC}[i:i+31])
VRT[i:i+31] \leftarrow \text{RoundToNearSP(} \text{prod +fp(}\text{VRB}[i:i+31]) \text{)}
end

For each integer value i from 0 to 3, do the following.
Single-precision floating-point element i in VRA is multiplied by single-precision floating-point
element i in VRC. Single-precision floating-point
element i in VRB is added to the infinitely-precise
product. The intermediate result is rounded to the
nearest single-precision floating-point number and
placed into word element i of VRT.

**Special Registers Altered:**
None

**Programming Note**
To use a multiply-add to perform an IEEE or Java
compliant multiply, the addend must be -0.0. This
is necessary to insure that the sign of a zero result
will be correct when the product is -0.0 (+0.0 + -0.0
\geq +0.0, and -0.0 + -0.0 \geq -0.0). When the sign of a
resulting 0.0 is not important, then +0.0 can be
used as an addend which may, in some cases,
avoid the need for a second register to hold a -0.0
in addition to the integer/floating-point +0.0 that
may already be available.

**Vector Negative Multiply-Subtract**

Single-Precision VA-form

\[
\text{vnmsubfp } \quad \text{VRT, VRA, VRC, VRB}
\]

<table>
<thead>
<tr>
<th>4</th>

<th>21</th>
<th>26</th>
<th>47</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>VRT</td>
<td>VRA</td>
<td>VRB</td>
<td>VRC</td>
<td>47</td>
<td></td>
</tr>
</tbody>
</table>

do i=0 to 127 by 32
prod_{i,inf} \leftarrow (\text{VRA}[i:i+31] \times \text{fp}(\text{VRC}[i:i+31])
VRT[i:i+31] \leftarrow \text{-RoundToNearSP(} \text{prod_{i,inf +fp(}\text{VRB}[i:i+31])} \text{)}
end

For each integer value i from 0 to 3, do the following.
Single-precision floating-point element i in VRA is multiplied by single-precision floating-point
element i in VRC. Single-precision floating-point
element i in VRB is subtracted from the
infinitely-precise product. The intermediate result
is rounded to the nearest single-precision floating-point
number, then negated and placed
into word element i of VRT.

**Special Registers Altered:**
None
5.10.2 Vector Floating-Point Maximum and Minimum Instructions

**Vector Maximum Single-Precision VX-form**

\[ \text{vmaxfp} \quad \text{VRT, VRA, VRB} \]

\[
\begin{array}{c|cccc|c}
4 & 6 & 11 & 16 & 21 & 1034 \\
\hline
0 & 10 & 10 & 10 & 10 & 10 \\
\end{array}
\]

For each integer value \( i \) from 0 to 3, do the following.

Single-precision floating-point element \( i \) in VRA is compared to single-precision floating-point element \( i \) in VRB. The larger of the two values is placed into word element \( i \) of VRT.

The maximum of +0 and -0 is +0. The maximum of any value and a NaN is a QNaN.

**Special Registers Altered:**

None

---

**Vector Minimum Single-Precision VX-form**

\[ \text{vminfp} \quad \text{VRT, VRA, VRB} \]

\[
\begin{array}{c|cccc|c}
4 & 6 & 11 & 16 & 21 & 1098 \\
\hline
0 & 10 & 10 & 10 & 10 & 10 \\
\end{array}
\]

For each integer value \( i \) from 0 to 3, do the following.

Single-precision floating-point element \( i \) in VRA is compared to single-precision floating-point element \( i \) in VRB. The smaller of the two values is placed into word element \( i \) of VRT.

The minimum of +0 and -0 is -0. The minimum of any value and a NaN is a QNaN.

**Special Registers Altered:**

None
5.10.3 Vector Floating-Point Rounding and Conversion Instructions

See Appendix C, “Vector RTL Functions [Category: Vector]” on page 701, for RTL function descriptions.

Vector Convert To Signed Fixed-Point Word Saturate VX-form

\[ \text{vctsxs} \quad \text{VRT,VRB,UIM} \]

<table>
<thead>
<tr>
<th>4</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>31</th>

\[
\text{do } i=0 \text{ to 127 by 32 } \\
\text{VRT}_{i:i+31} \leftarrow \text{ConvertSPtoSXW}saturate((\text{VRB})_{i:i+31}, \text{UIM}) \]

For each integer value \(i\) from 0 to 3, do the following.

- Single-precision floating-point word element \(i\) in VRB is multiplied by \(2^{\text{UIM}}\). The product is converted to a 32-bit signed fixed-point integer using the rounding mode Round toward Zero.
  - If the intermediate result is greater than \(2^{31}-1\) the result saturates to \(2^{31}-1\).
  - If the intermediate result is less than \(-2^{31}\) the result saturates to \(-2^{31}\).

The result is placed into word element \(i\) of VRT.

Special Registers Altered: SAT

do i=0 to 127 by 32
VRT0:31 ← RoundToSPIntFloor{(VRB)0:31}
end

For each integer value i from 0 to 3, do the following.
Single-precision floating-point element i in VRB is rounded to a single-precision floating-point integer using the rounding mode Round toward -Infinity.
The result is placed into the corresponding word element i of VRT.

Special Registers Altered:
None

Programming Note

The Vector Convert To Fixed-Point Word instructions support only the rounding mode Round toward Zero. A floating-point number can be converted to a fixed-point integer using any of the other three rounding modes by executing the appropriate Vector Round to Floating-Point Integer instruction before the Vector Convert To Fixed-Point Word instruction.

Programming Note

The fixed-point integers used by the Vector Convert instructions can be interpreted as consisting of 32-UIM integer bits followed by UIM fraction bits.

do i=0 to 127 by 32

VRT0:31 \ RoundToSPIntTrunc( (VRB)0:31 | 
end

For each integer value i from 0 to 3, do the following.

Single-precision floating-point element i in VRB is rounded to a single-precision floating-point integer using the rounding mode Round toward Zero.

The result is placed into the corresponding word element i of VRT.

**Special Registers Altered:**

None
5.10.4 Vector Floating-Point Compare Instructions

The Vector Floating-Point Compare instructions compare two Vector Registers word element by word element, interpreting the elements as single-precision floating-point numbers. With the exception of the Vector Compare Bounds Floating-Point instruction, they set the target Vector Register, and CR Field 6 if Rc=1, in the same manner as do the Vector Integer Compare instructions; see Section 5.9.2.

The Vector Compare Bounds Floating-Point instruction sets the target Vector Register, and CR Field 6 if Rc=1, to indicate whether the elements in VRA are within the bounds specified by the corresponding element in VRB, as explained in the instruction description. A single-precision floating-point value x is said to be “within the bounds” specified by a single-precision floating-point value y if -y ≤ x ≤ y.

---

**Vector Compare Bounds Single-Precision VC-form**

<table>
<thead>
<tr>
<th>vcmpbfp</th>
<th>VRT, VRA, VRB (Rc=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>vcmpbf</td>
<td>VRT, VRA, VRB (Rc=1)</td>
</tr>
</tbody>
</table>

For each integer value i from 0 to 3, do the following.

Single-precision floating-point word element i in VRA is compared to single-precision floating-point word element i in VRB. A 2-bit value is formed that indicates whether the element in VRA is within the bounds specified by the element in VRB, as follows.

- Bit 0 of the 2-bit value is set to 0 if the element in VRA is less than or equal to the element in VRB, and is set to 1 otherwise.
- Bit 1 of the 2-bit value is set to 0 if the element in VRA is greater than or equal to the negation of the element in VRB, and is set to 1 otherwise.

The 2-bit value is placed into the high-order two bits of word element i of VRT and the remaining bits of element i are set to 0.

If Rc=1, CR field 6 is set as follows.

**Bit Description**

| 0 | Set to 0 |
| 1 | Set to 0 |

**Programming Note**

Each single-precision floating-point word element in VRB should be non-negative; if it is negative, the corresponding element in VRA will necessarily be out of bounds.

One exception to this is when the value of an element in VRB is -0.0 and the value of the corresponding element in VRA is either +0.0 or -0.0. +0.0 and -0.0 compare equal to -0.0.
### Vector Compare Equal To

</tr>
<tr>
<td>6</td>
<td>11</td>
<td>16</td>
</tr>
<tr>
<td>21</td>
<td>31</td>
<td></td>
</tr>
</tbody>
</table>
```

For each integer value \( i \) from 0 to 3, do the following.

The single-precision floating-point estimate of \( 2 \) raised to the power of single-precision floating-point element \( i \) in VRB is placed into word element \( i \) of VRT.

Let \( x \) be any single-precision floating-point input value. Unless \( x < -146 \) or the single-precision floating-point result of computing \( 2 \) raised to the power \( x \) would be a zero, an infinity, or a QNaN, the estimate has a relative error in precision no greater than one part in 16. The most significant 12 bits of the estimate’s significand are monotonic. An integral input value returns an integral value when the result is representable.

The result for various special cases of the source value is given below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Infinity</td>
<td>+0</td>

<td>QNaN</td>
</tr>
</tbody>
</table>

**Special Registers Altered:**

None

**Vector Log Base 2 Estimate Floating-Point VX-form**

```
vlogefp VRT,VRB
```

```
<table>
<thead>
<tr>
<th>i</th>
<th>VRT</th>
<th>VRB</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td>458</td>
</tr>
<tr>
<td>6</td>
<td>11</td>
<td>16</td>
</tr>
<tr>
<td>21</td>
<td>31</td>
<td></td>
</tr>
</tbody>
</table>
```

For each integer value \( i \) from 0 to 3, do the following.

The single-precision floating-point estimate of the base 2 logarithm of single-precision floating-point element \( i \) in VRB is placed into the corresponding word element of VRT.

Let \( x \) be any single-precision floating-point input value. Unless \( |x-1| \leq 0.125 \) or the single-precision floating-point result of computing the base 2 logarithm of \( x \) would be an infinity or a QNaN, the estimate has an absolute error in precision (absolute value of the difference between the estimate and the infinitely precise value) no greater than \( 2^{-5} \). Under the same conditions, the estimate has a relative error in precision no greater than one part in 8.

The most significant 12 bits of the estimate’s significand are monotonic. The estimate is exact if \( x=2^y \), where \( y \) is an integer between -149 and +127 inclusive. Otherwise the value placed into the element of register VRT may vary between implementations, and between different executions on the same implementation.

The result for various special cases of the source value is given below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>

For each integer value \( i \) from 0 to 127, do the following.

The single-precision floating-point estimate of the reciprocal of single-precision floating-point element \( i \) in \( VRB \) is placed into word element \( i \) of \( VRT \).

Unless the single-precision floating-point result of computing the reciprocal of a value would be a zero, an infinity, or a QNaN, the estimate has a relative error in precision no greater than one part in \( 4096 \).

Note that results may vary between implementations, and between different executions on the same implementation.

The result for various special cases of the source value is given below.

<table>

    end
  end
  VR[VRT].dword[0] ← 0b0 || (prod[0] ^ prod[1])
```

For each integer value \( i \) from 0 to 3, do the following.

Let \( \text{prod}[i] \) be the 63-bit result of a binary polynomial multiplication of the contents of word element \( i \) of \( \text{VR}[\text{VRA}] \) and the contents of word element \( i \) of \( \text{VR}[\text{VRB}] \).

For each integer value \( i \) from 0 to 1, do the following.

The exclusive-OR of \( \text{prod}[2i] \) and \( \text{prod}[2i+1] \) is placed in bits 1:63 of doubleword element \( i \) of \( \text{VR}[\text{VRT}] \). Bit 0 of doubleword element \( i \) of \( \text{VR}[\text{VRT}] \) is set to 0.

</tr>
</tbody>
</table>

if MSR.VEC=0 then Vector_Unavailable()

do i = 0 to 15
    index ← VR[VRB].byte[i]
    if index < 128 then
        perm.bit[i] ← VR[VRA].bit[index]
    else
        perm.bit[i] ← 0
    end
VR[VRT].dword[0] ← Chop(EXTZ(perm),64)
VR[VRT].dword[1] ← 0x0000_0000_0000_0000

For each integer value \( i \) from 0 to 15, do the following.

Let \( \text{index} \) be the contents of byte element \( i \) of \( VR[VRB] \).

If \( \text{index} \) is less than 128, then the contents of bit \( i \) of \( VR[VRA] \) are placed into bit \( 48+i \) of double-word element \( i \) of \( VR[VRT] \). Otherwise, bit \( 48+i \) of doubleword element \( i \) of \( VR[VRT] \) is set to 0.

The contents of bits 0:47 of \( VR[VRT] \) are set to 0.
The contents of bits 63:127 of \( VR[VRT] \) are set to 0.

Special Registers Altered:
None

Programming Note

The fact that the permuted bit is 0 if the corresponding index value exceeds 127 permits the permuted bits to be selected from a 256-bit quantity, using a single index register. For example, assume that the 256-bit quantity \( Q \), from which the permuted bits are to be selected, is in registers \( v2 \) (high-order 128 bits of \( Q \)) and \( v3 \) (low-order 128 bits of \( Q \)), that the index values are in register \( v1 \), with each byte of \( v1 \) containing a value in the range 0:255, and that each byte of register \( v4 \) contains the value 128. The following code sequence selects eight permuted bits from \( Q \) and places them into the low-order byte of \( v6 \).

\[ \text{vbpermq v6,v1,v2} \quad \# \text{select from high-order half of } Q \]
\[ \text{xor v0,v1,v4} \quad \# \text{adjust index values} \]
\[ \text{vbpermq v5,v0,v3} \quad \# \text{select from low-order half of } Q \]
\[ \text{vor v6,v6,v5} \quad \# \text{merge the two selections} \]
5.16 Decimal Integer Arithmetic Instructions

The Decimal Integer Arithmetic instructions operate on decimal integer values only in signed packed decimal format. Signed packed decimal format consists of 31 4-bit base-10 digits of magnitude and a trailing 4-bit sign code. Operations are performed as sign-magnitude, and produce a decimal result placed in a Vector Register (i.e., \texttt{bcdadd}, \texttt{bcdsub}).

A valid encoding of a decimal integer value requires the following properties.
- Each of the 31 4-bit digits of the operand’s magnitude (bits 0:123) must be in the range 0-9.
- The sign code (bits 124:127) must be in the range 10-15.

Source operands with sign codes of \texttt{0b1010}, \texttt{0b1100}, \texttt{0b1110}, and \texttt{0b1111} are interpreted as positive values.

Source operands with sign codes of \texttt{0b1011} and \texttt{0b1101} are interpreted as negative values.

Positive and zero results are encoded with a either sign code of \texttt{0b1100} or \texttt{0b1111}, depending on the preferred sign (indicated as an immediate operand).

Negative results are encoded with a sign code of \texttt{0b1101}.

Chapter 6. Decimal Floating-Point [Category: Decimal Floating-Point]

6.1 Decimal Floating-Point (DFP) Facility Overview

This chapter describes the behavior of the decimal floating-point facility, the supported data types, formats, and classes, and the usage of registers. Also included are the execution model, exceptions, and instructions supported by the decimal floating-point facility.

The decimal floating-point (DFP) facility shares the 32 floating-point registers (FPRs) and the Floating-Point Status and Control Register (FPSCR) with the floating-point (BFP) facility. However, the interpretation of data formats in the FPRs, and the meaning of some control and status bits in the FPSCR are different between the BFP and DFP facilities.

The DFP facility also shares the Condition Register (CR) with the fixed-Point facility, the BFP facility, and the vector facility.

The DFP facility supports three DFP data formats: DFP Short (single precision), DFP Long (double precision), and DFP Extended (quad precision). Most operations are performed on DFP Long or DFP Extended format directly. Support for DFP Short is limited to conversion to and from DFP Long. Some DFP instructions operate on other data types, including signed or unsigned binary fixed-point data, and signed or unsigned decimal data.

DFP instructions are provided to perform arithmetic, compare, test, quantum-adjustment, conversion, and format operations on operands held in FPRs or FPR pairs.

- **Arithmetic instructions**
  These instructions perform addition, subtraction, multiplication, and division operations.

- **Compare instructions**
  These instructions perform a comparison operation on the numerical value of two DFP operands.

- **Test instructions**
  These instructions test the data class, the data group, the exponent, or the number of significant digits of a DFP operand.

- **Quantum-adjustment instructions**
  These instructions convert a DFP number to a result in the form that has the designated exponent, which may be explicitly or implicitly specified.

- **Conversion instructions**
  These instructions perform conversion between different data formats or data types.

- **Format instructions**
  These instructions facilitate composing or decomposing a DFP operand.

These instructions are described in Section 6.6 “DFP Instruction Descriptions” on page 288.

The three DFP data formats allow finite numbers to be represented with different precision and ranges. Special codes are also provided to represent +Infinity, -Infinite, Quiet NaN (Not-a-Number), and Signaling NaN. Operations involving infinities produce results obeying traditional mathematical conventions. NaNs have no mathematical interpretation. The encoding of NaNs provides a diagnostic information field. This diagnostic field may be used to indicate such things as the source of an uninitialized variable or the reason an invalid result was produced.

The DFP processor recognizes a set of DFP exceptions which are indicated via bits set in the FPSCR. Additionally, the DFP exception actions depend on the setting of the various exception enable bits in the FPSCR.

The following DFP exceptions are detected by the DFP processor. The exception status bits in the FPSCR are indicated in parentheses.

- **Invalid Operation Exception** (VX)
  SNaN (VXSNAN)
  $\infty \times \infty$ (VXISI)
  $\infty \div \infty$ (VXIDI)
  $0 \div 0$ (VXZDZ)
Each DFP exception and each category of Invalid Operation Exception has an exception status bit in the FPSCR. In addition, each of the five DFP exceptions has a corresponding enable bit in the FPSCR. These enable bits enable or disable the invocation of the system floating-point enabled exception error handler, and may affect the setting of some exception status bits in the FPSCR.

The usage of these bits by the DFP facility differs from the usage by the BFP facility. Section 6.5.10 “DFP Exceptions” on page 280 provides a detailed discussion of DFP exceptions, including the effects of the enable bits.

6.2 DFP Register Handling

The following sections describe first how the floating-point registers are utilized by the DFP facility. The subsequent section covers the DFP usage of CR and FPSCR.

6.2.1 DFP Usage of Floating-Point Registers

The DFP facility shares the same 32 64-bit FPRs with the BFP facility. Like the FP instructions, DFP instructions also use 5-bit fields for designating the FPRs to hold the source or target operands.

When data in DFP Short format is held in a FPR, it occupies the rightmost 32 bits of the FPR. The Load Floating-Point as Integer Word Algebraic instruction is provided to load the rightmost 32 bits of a FPR with a single-word data from storage. The Store Floating-Point as Integer Word instruction is available to store the rightmost 32 bits of a FPR to a storage location.

Data in DFP Long format, 64-bit binary fixed-point values, or 64-bit BCD values is held in a FPR using all 64 bits. Data of 64 bits may be loaded from storage via any of the Load Floating-Point Double instructions and stored via any of the Store Floating-Point Double instructions.

Data in DFP Extended format or 128-bit BCD values is held in an even-odd FPR pair using all 128 bits. Data of 128 bits must be loaded into the desired even-odd pair of floating-point registers using an appropriate sequence of the Load Floating-Point Double instructions and stored using an appropriate sequence of the Store Floating-Point Double instructions.

Data used as a source operand by any Decimal Floating-Point instruction that was produced, either directly or indirectly, by a Load Floating-Point Single instruction, a Floating Round to Single-Precision instruction, or a binary floating-point single-precision arithmetic instruction is boundedly undefined.

When an even-odd FPR pair is used to hold a 128-bit operand, the even-numbered FPR is used to hold the leftmost doubleword of the operand and the next higher-numbered FPR is used to hold the rightmost doubleword. A DFP instruction designating an odd-numbered FPR for a 128-bit operand is an invalid instruction form.

Programming Note

The Floating-Point Move instructions can be used to move operands between FPRs.

The bit definitions for the FPSCR are as follows.

Programming Note

FPSCR28 is reserved for extension of the DRN field, therefore DRN may be set using the mtfsf1 instruction to set the rounding mode.

Floating-Point Exception Summary (FX)
Every floating-point instruction, except mtfsfi and mtfsf, implicitly sets FPSCRFX to 1 if that instruction causes any of the floating-point exception bits in the FPSCR to change from 0 to 1. mcrfs, mtfsfi, mtfsf, mtfsf0, and mtfsf1 can alter FPSCRFX explicitly.

Floating-Point Enabled Exception Summary (FEX)
This bit is the OR of all the floating-point exception bits masked by their respective enable bits. mcrfs, mtfsfi, mtfsf, mtfsf0, and mtfsf1 cannot alter FPSCRFX explicitly.

Floating-Point Invalid Operation Exception Summary (VX)
This bit is the OR of all the Invalid Operation
exception bits. \textit{mcrfs}, \textit{mtfsfi}, \textit{mtfsf}, \textit{mtfsb0}, and \textit{mtfsb1} cannot alter \textit{FPSCRXX} explicitly.

35 \textbf{Floating-Point Overflow Exception} (OX) See Section 6.5.10.3, “Overflow Exception” on page 283.

36 \textbf{Floating-Point Underflow Exception} (UX) See Section 6.5.10.4, “Underflow Exception” on page 284.

37 \textbf{Floating-Point Zero Divide Exception} (ZX) See Section 6.5.10.2, “Zero Divide Exception” on page 283.

38 \textbf{Floating-Point Inexact Exception} (XX) See Section 6.5.10.5, “Inexact Exception” on page 285.

FPSCRXX is a sticky version of FPSCRFI (see below). Thus the following rules completely describe how FPSCRXX is set by a given instruction.

- If the instruction affects FPSCRFI, the new value of FPSCRXX is obtained by ORing the old value of FPSCRXX with the new value of FPSCRFI.
- If the instruction does not affect FPSCRFI, the value of FPSCRXX is unchanged.

39 \textbf{Floating-Point Invalid Operation Exception (SNaN)} (VXSNAN) See Section 6.5.10.1, “Invalid Operation Exception” on page 282.

40 \textbf{Floating-Point Invalid Operation Exception (∞ - ∞)} (VXISI) See Section 6.5.10.1.

41 \textbf{Floating-Point Invalid Operation Exception (∞ + ∞)} (VXIDI) See Section 6.5.10.1.

42 \textbf{Floating-Point Invalid Operation Exception (0/0)} (VXZDZ) See Section 6.5.10.1.

43 \textbf{Floating-Point Invalid Operation Exception (∞ × 0)} (VXMIZ) See Section 6.5.10.1.

44 \textbf{Floating-Point Invalid Operation Exception (Invalid Compare)} (VXVC) See Section 6.5.10.1.

45 \textbf{Floating-Point Fraction Rounded} (FR) The last Arithmetic or Rounding and Conversion instruction incremented the fraction during rounding. See Section 6.5.1, “Rounding” on page 276. This bit is not sticky.

46 \textbf{Floating-Point Fraction Inexact} (FI) The last Arithmetic or Rounding and Conversion instruction either produced an inexact result during rounding or caused a disabled Overflow Exception. See Section 6.5.1. This bit is not sticky.

47:51 \textbf{Floating-Point Result Flags} (FPRF)

- \textbf{Floating-Point Result Class Descriptor} (C)
  Arithmetic, rounding, and conversion instructions may set this bit with the FPCC bits, to indicate the class of the result as shown in Figure 71 on page 272.

48:51 \textbf{Floating-Point Condition Code} (FPCC)

- \textbf{Floating-Point Less Than or Negative} (FL or <)
- \textbf{Floating-Point Greater Than or Positive} (FG or >)
- \textbf{Floating-Point Equal or Zero} (FE or =)
- \textbf{Floating-Point Unordered or NaN} (FU or ?)

52 Reserved

53 \textbf{Floating-Point Invalid Operation Exception (Software Request)} (VXSOFT)
This bit can be altered only by \textit{mcrfs}, \textit{mtfsfi}, \textit{mtfsf}, \textit{mtfsb0}, or \textit{mtfsb1}. See Section 6.5.10.1, “Invalid Operation Exception” on page 282.

Neither used nor changed by DFP.

\textbf{Programming Note}

Although the architecture does not provide a DFP square root instruction, if software simulates such an instruction, it should set bit 54 whenever the source operand of the square root function is invalid.
Floating-Point Invalid Operation Exception Enable (VE)  
See Section 6.5.10.1.

Floating-Point Overflow Exception Enable (OE)  
See Section 6.5.10.3, “Overflow Exception” on page 283.

Floating-Point Underflow Exception Enable (UE)  
See Section 6.5.10.4, “Underflow Exception” on page 284.

Floating-Point Zero Divide Exception Enable (ZE)  
See Section 6.5.10.2, “Zero Divide Exception” on page 283.

Floating-Point Inexact Exception Enable (XE)  
See Section 6.5.10.5, “Inexact Exception” on page 285.

Reserved (not used by DFP)

Binary Floating-Point Rounding Control (RN)  
See Section 6.5.1, “Rounding” on page 276.

6.3 DFP Support for Non-DFP Data Types

In addition to the DFP data types, the DFP processor provides limited support for the following non-DFP data types: signed or unsigned binary fixed-point data, and signed or unsigned decimal data.

In unsigned binary fixed-point data, all bits are used to express the absolute value of the number. For signed binary fixed-point data, the leftmost bit represents the sign, which is followed by the numeric field. Positive numbers are represented in true binary notation with the sign bit set to zero. When the value is zero, all bits are zeros, including the sign bit. Negative numbers are represented in two's complement binary notation with a one in the sign-bit position.

For decimal data, each byte contains a pair of four-bit nibbles; each four-bit nibble contains a binary-coded-decimal (BCD) code. There are two kinds of BCD codes: digit code and sign code. For unsigned decimal data, all nibbles contain a digit code (D) as shown in Figure 72.

```
D D D D ... D D D D
```

Figure 72. Format for Unsigned Decimal Data

For signed decimal data, the rightmost nibble contains a sign code (S) and all other nibbles contain a digit code as shown in Figure 73.

```
D D D D ... D D D D S
```

Figure 73. Format for Signed Decimal Data

The decimal digits 0-9 have the binary encoding 0000-1001. The preferred plus-sign codes are 1100 and 1111. The preferred minus sign code is 1101. These are the sign codes generated for the results of the `Decode DPD To BCD` instruction. A selection is provided by this instruction to specify which of the two preferred plus sign codes is to be generated. Alternate sign codes are also recognized as valid in the sign position: 1010 and 1110 are alternate sign codes for plus, and 1011 is an alternate sign code for minus. Alternate sign codes are accepted for any source operand, but are not generated as a result by the instruction. When an invalid digit or sign code is detected by the `Encode BCD To DPD` instruction, an invalid-opera-
tion exception occurs. A summary of digit and sign codes are provided in Figure 74.

Figure 74. Summary of BCD Digit and Sign Codes

### 6.4 DFP Number Representation

A DFP finite number consists of three components: a sign bit, a signed exponent, and a significand. The signed exponent is a signed binary integer. The significand consists of a number of decimal digits, which are to the left of the implied decimal point. The rightmost digit of the significand is called the units digit. The numerical value of a DFP finite number is represented as $(-1)^{sign} \times significand \times 10^{exponent}$, and the unit value of this number is $(1 \times 10^{exponent})$, which is called the quantum.

DFP finite numbers are not normalized. This allows leading zeros and trailing zeros to exist in the significand. This unnormalized DFP number representation allows some values to have redundant forms; each form represents the DFP number with a different combination of the significand value and the exponent value. For example, $1000000 \times 10^5$ and $10 \times 10^{10}$ are two different forms of the same numerical value. A form of this number representation carries information about both the numerical value and the quantum of a DFP finite number.

The significant digits of a DFP finite number are the digits in the significand beginning with the leftmost non-zero digit and ending with the units digit.

### 6.4.1 DFP Data Format

DFP numbers and NaNs may be represented in FPRs in any of the three data formats: DFP Short, DFP Long, or DFP Extended. The contents of each data format represent encoded information. Special codes are assigned to NaNs and infinities. Different formats support different sizes in both significand and exponent. Arithmetic, compare, test, quantum-adjustment, and format instructions are provided for DFP Long and DFP Extended formats only.

The sign is encoded as a one bit binary value. Significand is encoded as an unsigned decimal integer in two distinct parts. The leftmost digit (LMD) of the significand is encoded as part of the combination field; the remaining digits of the significand are encoded in the trailing significand field. The exponent is contained in the combination field in two parts. However, prior to encoding, the exponent is converted to an unsigned binary value called the biased exponent by adding a bias value which is a constant for each format. The two leftmost bits of the biased exponent are encoded with the leftmost digit of the significand in the leftmost bits of the combination field. The rest of the biased exponent occupies the remaining portion of the combination field.

### 6.4.1.1 Fields Within the Data Format

The DFP data representation comprises three fields, as diagrammed below for each of the three formats:

**DFP Short format**

```
  S  G  T
0  1  12 31
```

Figure 75. DFP Short format

**DFP Long format**

```
  S  G  T
0  1  14 63
```

Figure 76. DFP Long format

**DFP Extended format**

```
  S  G  T (continued)
0  1  18 63
```

Figure 77. DFP Extended format

The fields are defined as follows:

**Sign bit (S)**
The sign bit is in bit 0 of each format, and is zero for plus and one for minus.

**Combination field (G)**
As the name implies, this field provides a combination of the exponent and the left-most digit (LMD) of the significand, for finite numbers, or provides a special code
for denoting the value as either a Not-a-Number or an Infinity.

The first 5 bits of the combination field contain the encoding of NaN or infinity, or the two leftmost bits of the biased exponent and the leftmost digit (LMD) of the significand. The following tables show the encoding:

<table>
<thead>
<tr>
<th>G0:4</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>11111</td>

</tr>
<tr>
<td>9</td>
<td>11001   11011   11101</td>
</tr>
</tbody>
</table>

**Figure 79. Encoding of bits 0:4 of the G field for Finite Numbers**

For DFP finite numbers, the rightmost N-5 bits of the N-bit combination field contain the remaining bits of the *biased exponent*. For NaNs, bit 5 of the combination field is used to distinguish a Quiet NaN from a Signaling NaN; the remaining bits in a source operand are ignored and they are set to zeros in a target operand by most operations. For infinities, the rightmost N-5 bits of the N-bit combination field of a source operand are ignored and they are set to zeros in a target operand by most operations.

**Trailing Significand field** (T)

For DFP finite numbers, this field contains the remaining *significand* digits. For NaNs, this field may be used to contain diagnostic information. For infinities, contents in this field of a source operand are ignored and they are set to zeros in a target operand by most operations. The trailing significand field is a multiple of 10-bit blocks. The multiple depends on the format. Each 10-bit block is called a declet and represents three decimal digits, using the Densely Packed Decimal (DPD) encoding defined in Appendix B.

### 6.4.1.2 Summary of DFP Data Formats

The properties of the three DFP formats are summarized in the following table:

</tbody>
</table>
6.4.1.3 Preferred DPD Encoding

Execution of DFP instructions decodes source operands from DFP data formats to an internal format for processing, and encodes the operation result before the final result is returned as the target operand.

As part of the decoding process, declets in the trailing significand field of source operands are decoded to their corresponding BCD digit codes using the DPD-to-BCD decoding algorithm. As part of the encoding process, BCD digit codes to be stored into the trailing significand field of the target operand are encoded into declets using the BCD-to-DPD encoding algorithm. Both the decoding and encoding algorithms are defined in Appendix B.

As explained in Appendix B, there are eight 3-digit decimal values that have redundant DPD codes and one preferred DPD code. All redundant DPD codes are recognized in source operands for the associated 3-digit decimal number. DFP operations will always generate the preferred DPD codes for the trailing significand field of the target operand.

6.4.2 Classes of DFP Data

There are six classes of DFP data, which include numerical and nonnumeric entities. The numerical entities include zero, subnormal number, normal number, and infinity data classes. The nonnumeric entities include quiet and signaling NaNs data classes. The value of a DFP finite number, including zero, subnormal number, and normal number, is a quantization of the real number based on the data format. The Test Data Class instruction may be used to determine the class of a DFP operand. In general, an operation that returns a DFP result sets the FPCR.FPRF field to indicate the data class of the result.

The following tables show the value ranges for finite-number data classes, and the codes for NaNs and infinities.

<table>
<thead>
<tr>
<th>Format</th>
<th>DFP Short</th>
<th>DFP Long</th>
<th>DFP Extended</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum subnormal number ($D_{\text{min}}$)</td>
<td>$1 \times 10^{-101}$</td>
<td>$1 \times 10^{-398}$</td>
<td>$1 \times 10^{-6176}$</td>
</tr>
</tbody>
</table>

Figure 80. Summary of DFP Formats
Zeros have a zero significand and any representable value in the exponent. A +0 is distinct from -0, and zeros with different exponents are distinct, except that comparison treats them as equal.

Subnormal Numbers
Subnormal numbers have values that are smaller than $N_{\text{min}}$ and greater than zero in magnitude.

Normal Numbers
Normal numbers are nonzero finite numbers whose magnitude is between $N_{\text{min}}$ and $N_{\text{max}}$ inclusively.

Infinities
Infinities are represented by 0b11110 in the leftmost 5 bits of the combination field. When an operation is defined to generate an infinity as the result, a default infinity is sometimes supplied. A default infinity has all remaining bits in the combination field and trailing significand field set to zeros.

When infinities are used as source operands, only the leftmost 5 bits of the combination field are interpreted (i.e., 0b11110 indicates the value is an infinity). The trailing significand field of infinities is usually ignored. For generated infinities, the leftmost 5 bits of the combination field are set to 0b11110 and all remaining combination bits are set to zero.

Infinities can participate in most arithmetic operations and give a consistent result. In comparisons, any +Infinity compares greater than any finite number, and any -Infinity compares less than any finite number. All +Infinity are compared equal and all -Infinity are compared equal.

Signaling and Quiet NaNs
There are two types of Not-a-Numbers (NaNs), Signaling (SNaN) and Quiet (QNaN).

A special QNaN is sometimes supplied as the default QNaN for a disabled invalid-operation exception; it has a plus sign, the leftmost 6 bits of the combination field set to 0b111110 and remaining bits in the combination field and the trailing significand field set to zero.

Normally, source QNaNs are propagated during operations so that they will remain visible at the end. When a QNaN is propagated, the sign is preserved, the decimal value of the trailing significand field is preserved but reencoded using the preferred DPD codes, and the contents in the rightmost N-6 bits of the combination field set to zero, where N is the width of the combination field for the format.

A source SNaN generally causes an invalid-operation exception. If the exception is disabled, the SNaN is converted to the corresponding QNaN and propagated. The primary encoding difference between an SNaN and a QNaN is that bit 5 of an SNaN is 1 and bit 5 of a QNaN is 0. When an SNaN is propagated as a QNaN, bit 5 is set to 0, and, just as with QNaN propagation, the sign is preserved, the decimal value of the trailing significand field is preserved but reencoded using the preferred DPD codes, and the contents in the rightmost N-6 bits of the combination field set to zero, where N is the width of the combination field for the format. For some format-conversion instructions, a source SNaN does not cause an invalid-operation exception, and an SNaN is returned as the target operand.

For instructions with two source NaNs and a NaN is to be propagated as the result, do the following:
- If there is a QNaN in FRA and an SNaN in FRB, the SNaN in FRB is propagated.
- Otherwise, propagate the NaN in FRA.

6.5 DFP Execution Model

DFP operations are performed as if they first produce an intermediate result correct to infinite precision and with unbounded range. The intermediate result is then rounded to the destination's precision according to one of the eight DFP rounding modes. If the rounded result has only one form, it is delivered as the final result; if the rounded result has redundant forms, then an ideal exponent is used to select the form of the final result. The ideal exponent determines the form, not the value, of the final result. (See Section 6.5.3 "Formation of Final Result" on page 278.)

6.5.1 Rounding

Rounding takes a number regarded as infinitely precise and, if necessary, modifies it to fit the destination's precision. The destination's precision of an operation defines the set of permissible resultant values. For
most operations, the destination’s precision is the target-format precision and the permissible resultant values are those values representable in the target format. For some special operations, the destination precision is constrained by both the target format and some additional restrictions, and the permissible resultant values are a subset of the values representable in the target format.

Rounding sets FPSCR bits FR and FI. When an inexact exception occurs, FI is set to one; otherwise, FI is set to zero. When an inexact exception occurs and if the rounded result is greater in magnitude than the intermediate result, then FR is set to one; otherwise, FR is set to zero. The exception is the Round to FP Integer Without Inexact instruction, which always sets FR and FI to zero. Rounding may cause an overflow exception or underflow exception; it may also cause an inexact exception.

Refer to Figure 83 below for rounding. Let Z be the intermediate result of a DFP operation. Z may or may not fit in the destination’s precision. If Z is exactly one of the permissible representable resultant values, then the final result in all rounding modes is Z. Otherwise, either Z1 or Z2 is chosen to approximate the result, where Z1 and Z2 are the next larger and smaller permissible resultant values, respectively.

![Figure 83. Rounding](image)

**Round to Nearest, Ties to Even**
Choose the value that is closer to Z (Z1 or Z2). In case of a tie, choose the larger in magnitude (Z1 or Z2).

**Round to Nearest, Ties toward 0**
Choose the value that is closer to Z (Z1 or Z2). In case of a tie, choose the smaller in magnitude (Z1 or Z2).

**Round toward +∞**
Choose Z1.

**Round toward -∞**
Choose Z2.

**Round to Nearest, Ties away from 0**
Choose the value that is closer to Z (Z1 or Z2). In case of a tie, choose the larger in magnitude (Z1 or Z2). However, an infinitely precise result with magnitude at least \((N_{\text{max}} + 0.5Q(N_{\text{max}}))\) is rounded to infinity with no change in sign; where \(Q(N_{\text{max}})\) is the quantum of \(N_{\text{max}}\).

**Round to FP Integer**
Choose the value that is closer to Z (Z1 or Z2). In case of a tie, choose the smaller in magnitude (Z1 or Z2). However, an infinitely precise result with magnitude greater than \((N_{\text{max}} + 0.5Q(N_{\text{max}}))\) is rounded to infinity with no change in sign; where \(Q(N_{\text{max}})\) is the quantum of \(N_{\text{max}}\).

**Round away from 0**
Choose the larger in magnitude (Z1 or Z2).

**Round to prepare for shorter precision**
Choose the smaller in magnitude (Z1 or Z2). If the selected value is inexact and the units digit of the selected value is either 0 or 5, then the digit is incremented by one and the incremented result is delivered. In all other cases, the selected value is delivered. When a value has redundant forms, the units digit is determined by using the form that has the smallest exponent.

### 6.5.2 Rounding Mode Specification

Unless otherwise specified in the instruction definition, the rounding mode used by an operation is specified in the DFP rounding control (DRN) field of the FPSCR. The eight DFP rounding modes are encoded in the DRN field as specified in the table below.

<table>
<thead>
<tr>
<th>DRN</th>
<th>Rounding Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>

</tbody>
</table>

**Figure 84. Encoding of DFP Rounding-Mode Control (DRN)**

For the quantum-adjustment, a 2-bit immediate field, called RMC (Rounding Mode Control), in the instruction specifies the rounding mode used. The RMC field may contain a primary encoding or a secondary encoding. For Quantize, Quantize Immediate, and Reround, the RMC field contains the primary encoding. For Round to FP Integer the field contains either encoding, depending on the setting of a RMC-encoding-selection.
The following tables define the primary encoding and the secondary encoding.

**Figure 85. Primary Encoding of Rounding-Mode Control**

**6.5.3 Formation of Final Result**

An ideal exponent is defined for each DFP instruction that returns a DFP data operand.

**6.5.3.1 Use of Ideal Exponent**

For all DFP operations,

- if the rounded intermediate result has only one form, then that form is delivered as the final result.
- if the rounded intermediate result has redundant forms and is exact, then the form with the exponent closest to the ideal exponent is delivered.
- if the rounded intermediate result has redundant forms and is inexact, then the form with the smallest exponent is delivered.

The following table specifies the ideal exponent for each instruction.

**Figure 87. Summary of Ideal Exponents**

**6.5.4 Arithmetic Operations**

Four arithmetic operations are provided: Add, Subtract, Multiply, and Divide.

**6.5.4.1 Sign of Arithmetic Result**

The following rules govern the sign of an arithmetic operation when the operation does not yield an exception. They apply even when the operands or results are zeros or infinities.

- The sign of the result of an add operation is the sign of the source operand having the larger absolute value. If both source operands have the same sign, the sign of the result of an add operation is the same as the sign of the source operands. When the sum of two operands with opposite signs is exactly zero, the sign of the result is positive in all rounding modes except Round toward $-\infty$, in which case the sign is negative.

- The sign of the result of the subtract operation $x - y$ is the same as the sign of the result of the add operation $x + (-y)$.

- The sign of the result of a multiply or divide operation is the exclusive-OR of the signs of the source operands.
6.5.5 Compare Operations

Two sets of instructions are provided for comparing numerical values: Compare Ordered and Compare Unordered. In the absence of NaNs, these instructions work the same. These instructions work differently when either of the followings is true:

1. At least one source operand of the instruction is an SNaN and the invalid-operation exception is disabled.
2. When there is no SNaN in any source operand, at least one source operand of the instruction is a QNaN.

In case 1, Compare Unordered recognizes an invalid-operation exception and sets the FPSCRVXSNAN flag, but Compare Ordered recognizes the exception and sets both the FPSCRVXSNAN and FPSCRVXVC flags. In case 2, Compare Unordered does not recognize an exception, but Compare Ordered recognizes an invalid-operation exception and sets the FPSCRVXVC flag.

For finite numbers, comparisons are performed on values, that is, all redundant forms of a DFP number are treated equal.

Comparisons are always exact and cannot cause an inexact exception.

Comparison ignores the sign of zero, that is, +0 equals -0.

Infinities with like sign compare equal, that is, +∞ equals +∞, and -∞ equals -∞.

A NaN compares as unordered with any other operand, whether a finite number, an infinity, or another NaN, including itself.

Execution of a compare instruction always completes, regardless of whether any DFP exception occurs or not, and whether the exception is enabled or not.

6.5.6 Test Operations

Four kinds of test operations are provided: Test Data Class, Test Data Group, Test Exponent, and Test Significance.

The Test Data Class instruction examines the contents of a source operand and determines if the operand is one of the specified data classes. The test result and the sign of the source operand are indicated in the FPSCRFPCC field and CR field BF.

The Test Data Group instruction examines the contents of a source operand and determines if the operand is one of the specified data groups. The test result and the sign of the source operand are indicated in the FPSCRFPCC field and CR field BF.

The Test Exponent instruction compares the exponent of the two source operands. The test operation ignores the sign and significand of operands. Infinities compare equal, and NaNs compare equal. The test result is indicated in the FPSCRFPCC field and CR field BF.

The Test Significance instruction compares the number of significant digits of one source operand with the referenced number of significant digits in another source operand. The test result is indicated in the FPSCRFPCC field and CR field BF.

Execution of a test instruction does not cause any DFP exception.

6.5.7 Quantum Adjustment Operations

Four kinds of quantum-adjustment operations are provided: Quantize, Quantize Immediate, Reround, and Round To FP Integer. Each of them has an immediate field which specifies whether the rounding mode in FPSCR or a different one is to be used.

The Quantize instruction is used to adjust a DFP number to the form that has the specified target exponent. The Quantize Immediate instruction is similar to the Quantize instruction, except that the target exponent is specified in a 5-bit immediate field as a signed binary integer and has a limited range.

The Reround instruction is used to simulate a DFP operation of a precision other than that of DFP Long or DFP Extended. For the Reround instruction to produce a result which accurately reflects that which would have resulted from a DFP operation of the desired precision d in the range {1: 33} inclusively, the following conditions must be met:

- The precision of the preceding DFP operation must be at least one digit larger than d.
- The rounding mode used by the preceding DFP operation must be round-to-prepare-for-shorter-precision.

The Round To FP Integer instruction is used to round a DFP number to an integer value of the same format. The target exponent is implicitly specified, and is greater than or equal to zero.

6.5.8 Conversion Operations

There are two kinds of conversion operations: data-format conversion and data-type conversion.

6.5.8.1 Data-Format Conversion

The instructions Convert To DFP Long and Convert To DFP Extended convert DFP operands to wider formats; the instructions Round To DFP Short and Round To DFP Long convert DFP operands to narrower formats.

When converting a finite number to a wider format, the result is exact. When converting a finite number to a
narrower format, the source operand is rounded to the
target-format precision, which is specified by the
instruction, not by the target register size.

When converting a finite number, the ideal exponent of
the result is the source exponent.

Conversion of an infinity or NaN to a different format
does not preserve the source combination field. Let N
be the width of the target format's combination field.

- When the result is an infinity or a QNaN, the con-
tents of the rightmost N-5 bits of the N-bit target
combination field are set to zero.

- When the result is an SNaN, bit 5 of the target for-
mats combination field is set to one and the right-
most N-6 bits of the N-bit target combination field
are set to zero.

When converting a NaN to a wider format or when con-
verting an infinity from DFP Short to DFP Long, digits in
the source trailing significand field are reencoded using
the preferred DPD codes with sufficient zeros
 appended on the left to form the target trailing signifi-
cand field. When converting a NaN to a narrower for-
mater format or when converting an infinity from DFP Long to
DFP Short, the appropriate number of leftmost digits of
the source trailing significand field are removed and the
remaining digits of the field are reencoded using the
preferred DPD codes to form the target trailing signifi-
cand field.

When converting an infinity between DFP Long and
DFP Extended, a default infinity with the same sign is
produced.

When converting an SNaN between DFP Short and
DFP Long, it is converted to an SNaN without causing
an invalid-operation exception. When converting an
SNaN between DFP Long and DFP Extended, the
invalid-operation exception occurs; if the invalid-opera-
tion exception is disabled, the result is converted to the
corresponding QNaN.

### 6.5.8.2 Data-Type Conversion

The instructions Convert From Fixed and Convert To
Fixed are provided to convert a number between the
DFP data type and the signed 64-bit binary-integer
data type.

Conversion of a signed 64-bit binary integer to a DFP
Extended number is always exact.

Conversion of a DFP number to a signed 64-bit binary
integer results in an invalid-operation exception when
the converted value does not fit into the target format,
or when the source operand is an infinity or NaN. When
the exception is disabled, the most positive integer is
returned if the source operand is a positive number or
\( +\infty \), and the most negative integer is returned if the
source operand is a negative number, \( -\infty \), or NaN.

### 6.5.9 Format Operations

The format instructions are provided to facilitate com-
posing or decomposing a DFP number, and consist of
Encode BCD To DPD, Decode DPD To BCD, Extract
Biased Exponent, Insert Biased Exponent, Shift Signifi-
cand Left Immediate, and Shift Significand Right Imme-
diate. A source operand of SNaN does not cause an
invalid-operation exception, and an SNaN may be pro-
duced as the target operand.

### 6.5.10 DFP Exceptions

This architecture defines the following DFP exceptions:

- Invalid Operation Exception
  - SNaN
  - \( \infty \pm \infty \)
  - \( 0 \div 0 \)
  - \( \infty \times 0 \)
  - Invalid Compare
  - Invalid Conversion

- Zero Divide Exception
- Overflow Exception
- Underflow Exception
- Inexact Exception

These exceptions may occur during execution of a DFP
instruction.

Each DFP exception, and each category of the Invalid
Operation Exception, has an exception status bit in the
FPSCR. In addition, each DFP exception has a corre-
sponding enable bit in the FPSCR. The exception sta-
tus bit indicates occurrence of the corresponding
exception. If an exception occurs, the corresponding
enable bit governs the result produced by the instruc-
tion and, in conjunction with the FE0 and FE1 bits (see
the discussion of FE0 and FE1 below), whether and
how the system floating-point enabled exception error
handler is invoked. (In general, the enabling specified
by the enable bit is of invoking the system error handler,
not of permitting the exception to occur. The occur-
rence of an exception depends only on the instruction
and its source operands, not on the setting of any con-
tral bits. The only deviation from this general rule is that
the occurrence of an Underflow Exception may depend
on the setting of the enable bit.)

A single instruction, other than `mtfsfi` or `mtfsf`, may set
more than one exception bit only in the following cases:

- Inexact Exception may be set with Overflow
  Exception.
- Inexact Exception may be set with Underflow
  Exception.
- Invalid Operation Exception (SNaN) may be set
  with Invalid Operation Exception (Invalid Compare)
  for Compare Ordered instructions.
Invalid Operation Exception (SNaN) may be set with Invalid Operation Exception (Invalid Conversion) for Convert To Fixed instructions.

When an exception occurs the instruction execution may be completed or partially completed, depending on the exception and the operation.

For all instructions, except for the Compare and Test instructions, the following exceptions cause the instruction execution to be partially completed. That is, setting of CR field 1 (when Rc=1) and exception status flags is performed, but no result is stored into the target FPR or FPR pair. For Compare and Test instructions, instruction execution is always completed, regardless of whether any DFP exception occurs or not, and whether the exception is enabled or not.

- Enabled Invalid Operation
- Enabled Zero Divide

For the remaining kinds of exceptions, instruction execution is completed, a result, if specified by the instruction, is generated and stored into the target FPR or FPR pair, and appropriate status flags are set. The result may be a different value for the enabled and disabled conditions for some of these exceptions. The kinds of exceptions that deliver a result in target FPR are the following:

- Disabled Invalid Operation
- Disabled Zero Divide
- Disabled Overflow
- Disabled Underflow
- Disabled Inexact
- Enabled Overflow
- Enabled Underflow
- Enabled Inexact

Subsequent sections define each of the DFP exceptions and specify the action that is taken when they are detected.

The IEEE standard specifies the handling of exceptional conditions in terms of “traps” and “trap handlers”. In this architecture, a FPSCR exception enable bit of 1 causes generation of the result value specified in the IEEE standard for the “trap enabled” case: the expectation is that the exception will be detected by software, which will revise the result. A FPSCR exception enable bit of 0 causes generation of the “default result” value specified for the “trap disabled” (or “no trap occurs” or “trap is not implemented”) case: the expectation is that the exception will not be detected by software, which will simply use the default result. The result to be delivered in each case for each exception is described in the sections below.

The IEEE default behavior when an exception occurs is to generate a default value and not to notify software. In this architecture, if the IEEE default behavior when an exception occurs is desired for all exceptions, all FPSCR exception enable bits should be set to zero and Ignore Exceptions Mode (see below) should be used.

In this case the system floating-point enabled exception error handler is not invoked, even if DFP exceptions occur: software can inspect the FPSCR exception bits if necessary, to determine whether exceptions have occurred.

In this architecture, if software is to be notified that a given kind of exception has occurred, the corresponding FPSCR exception enable bit must be set to one and a mode other than Ignore Exceptions Mode must be used. In this case the system floating-point enabled exception error handler is invoked if an enabled DFP exception occurs. The system floating-point enabled exception error handler is also invoked if a Move To FPSCR instruction causes an exception bit and the corresponding enable bit both to be 1; the Move To FPSCR instruction is considered to cause the enabled exception.

The FE0 and FE1 bits control whether and how the system floating-point enabled exception error handler is invoked if an enabled DFP exception occurs. The location of these bits and the requirements for altering them are described in Book III, Power AS Operating Environment Architecture. (The system floating-point enabled exception error handler is never invoked because of a disabled DFP exception.) The effects of the four possible settings of these bits are as follows.

<table>
<thead>
<tr>
<th>FE0</th>
<th>FE1</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Ignore Exceptions Mode</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Imprecise Nonrecoverable Mode</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Imprecise Recoverable Mode</td>
</tr>
</tbody>
</table>

DFP exceptions do not cause the system floating-point enabled exception error handler to be invoked.

The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. It may not be possible to identify the excepting instruction or the data that caused the exception. Results produced by the excepting instruction may have been used by or may have affected subsequent instructions that are executed before the error handler is invoked.

The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. Sufficient information is provided to the error handler that it can identify the excepting instruction and the operands, and correct the result. No results produced by the excepting instruction have been used by or have affected subsequent instructions that are executed before the error handler is invoked.
In all cases, the question of whether a DFP result is stored, and what value is stored, is governed by the FPSCR exception enable bits, as described in subsequent sections, and is not affected by the value of the FE0 and FE1 bits.

In all cases in which the system floating-point enabled exception error handler is invoked, all instructions before the instruction at which the system floating-point enabled exception error handler is invoked have completed, and no instruction after the instruction at which the system floating-point enabled exception error handler is invoked has begun execution. (Recall that, for the two Imprecise modes, the instruction at which the system floating-point enabled exception error handler is invoked need not be the instruction that caused the exception.) The instruction at which the system floating-point enabled exception error handler is invoked has not been executed unless it is the excepting instruction, in which case it has been executed if the exception is not among those listed on page 280 as suppressed.

### Programming Note

In the ignore and both imprecise modes, a Floating-Point Status and Control Register instruction can be used to force any exceptions, due to instructions initiated before the Floating-Point Status and Control Register instruction, to be recorded in the FPSCR. (This forcing is superfluous for Precise Mode.)

In either of the Imprecise modes, a Floating-Point Status and Control Register instruction can be used to force any invocations of the system floating-point enabled exception error handler, due to instructions initiated before the Floating-Point Status and Control Register instruction, to occur. (This forcing has no effect in Ignore Exceptions Mode, and is superfluous for Precise Mode.)

In order to obtain the best performance across the widest range of implementations, the programmer should obey the following guidelines.

- If the IEEE default results are acceptable to the application, Ignore Exceptions Mode should be used with all FPSCR exception enable bits set to zero.
- If the IEEE default results are not acceptable to the application, Imprecise Nonrecoverable Mode should be used, or Imprecise Recoverable Mode if recoverability is needed, with FPSCR exception enable bits set to one for those exceptions for which the system floating-point enabled exception error handler is to be invoked.
- Ignore Exceptions Mode should not, in general, be used when any FPSCR exception enable bits are set to one.
- Precise Mode may degrade performance in some implementations, perhaps substantially, and therefore should be used only for debugging and other specialized applications.

#### 6.5.10.1 Invalid Operation Exception

**Definition**

An Invalid Operation Exception occurs when an operand is invalid for the specified DFP operation. The invalid DFP operations are:

- Any DFP operation on a signaling NaN (SNaN), except for Test, Round To DFP Short, Convert To DFP Long, Decode DPD To BCD, Extract Biased Exponent, Insert Biased Exponent, Shift Significand Left Immediate, and Shift Significand Right Immediate
- For add or subtract operations, magnitude subtraction of infinities \((+\infty) + (-\infty)\)
- Division of infinity by infinity \((\infty \div \infty)\)
- Division of zero by zero \((0 \div 0)\)
- Multiplication of infinity by zero \((\infty \times 0)\)
- Ordered comparison involving a NaN (Invalid Compare)
- The Quantize operation detects that the significand associated with the specified target exponent would have more significant digits than the target-format precision
- For the Quantize operation, when one source operand specifies an infinity and the other specifies a finite number
- The Reround operation detects that the target exponent associated with the specified target significance would be greater than \(X_{\text{max}}\)
- The Encode BCD To DPD operation detects an invalid BCD digit or sign code
- The Convert To Fixed operation involving a number too large in magnitude to be represented in the target format, or involving a NaN.
Chapter 6. Decimal Floating-Point [Category: Decimal Floating-Point]

6.5.10.2 Zero Divide Exception

Definition

A Zero Divide Exception occurs when a Divide instruction is executed with a zero divisor value and a finite nonzero dividend value.

Action

The action to be taken depends on the setting of the Zero Divide Exception Enable bit of the FPSCR.

When Zero Divide Exception is enabled (FPSCR ZE=1) and Zero Divide occurs, the following actions are taken:

1. Zero Divide Exception is set
   \[ \text{FPSCR}_{Z} = 1 \]
2. The target FPR is unchanged
3. FPSCR FR and FPRF are set to zero
4. FPSCR FPRF is set to indicate the class and sign of the result (±\(\infty\))

When Zero Divide Exception is disabled (FPSCR ZE=0) and Zero Divide occurs, the following actions are taken:

1. Zero Divide Exception is set
   \[ \text{FPSCR}_{Z} = 1 \]
2. The target FPR is set to ±\(\infty\), where the sign is determined by the XOR of the signs of the operands
3. FPSCR FR and FPRF are set to zero
4. FPSCR FPRF is set to indicate the class and sign of the result (±\(\infty\))

6.5.10.3 Overflow Exception

Definition

An overflow exception occurs whenever the target format's largest finite number is exceeded in magnitude by what would have been the rounded result if the exponent range were unbounded.

Action

Except for \text{Reround}, the following describes the handling of the IEEE overflow exception condition. The \text{Reround} operation does not recognize an overflow exception condition.

The action to be taken depends on the setting of the Overflow Exception Enable bit of the FPSCR.
When Overflow Exception is enabled (FPSCR\textsubscript{OE}=1) and overflow occurs, the following actions are taken:

1. Overflow Exception is set
   \( \text{FPSCR}_{OX} \leftarrow 1 \)
2. The infinitely precise result is divided by \(10^\alpha\). That is, the exponent adjustment \(\alpha\) is subtracted from the exponent. This is called the \emph{wrapped result}. The exponent adjustment for all operations, except for \emph{Round To DFP Short} and \emph{Round To DFP Long}, is 576 for DFP Long and 9216 for DFP Extended. For \emph{Round To DFP Short} and \emph{Round To DFP Long}, the exponent adjustment is 192 for the source format of DFP Long and 3072 for the source format of DFP Extended.
3. The wrapped result is rounded to the target-format precision. This is called the \emph{wrapped rounded result}.
4. If the wrapped rounded result has only one form, it is the delivered result. If the wrapped rounded result has redundant forms and is exact, the result of the form that has the exponent closest to the wrapped ideal exponent is returned. The wrapped ideal exponent is the result of subtracting the exponent adjustment from the ideal exponent.
5. FPSCR\textsubscript{FPRF} is set to indicate the class and sign of the result (± Normal Number)

When Overflow Exception is disabled (FPSCR\textsubscript{OE}=0) and overflow occurs, the following actions are taken:

1. Overflow Exception is set
   \( \text{FPSCR}_{OX} \leftarrow 1 \)
2. Inexact Exception is set
   \( \text{FPSCR}_{XX} \leftarrow 1 \)
3. The result is determined by the rounding mode and the sign of the intermediate result as follows.
4. The result is placed into the target FPR
5. FPSCR\textsubscript{FR} is set to one if the returned result is \(± \infty\), and is set to zero if the returned result is \(±N_{\text{max}}\)
6. FPSCR\textsubscript{FI} is set to one
7. FPSCR\textsubscript{FPPF} is set to indicate the class and sign of the result (± \infty or ± Normal number)

### 6.5.10.4 Underflow Exception

#### Definition

Except for \emph{Reround}, the following describes the handling of the IEEE underflow exception condition. The \emph{Reround} operation does not recognize an underflow exception condition.

The Underflow Exception is defined differently for the enabled and disabled states. However, a tininess condition is recognized in both states when a result computed as though both the precision and exponent range were unbounded would be nonzero and less than the target format’s smallest normal number, \(N_{\text{min}}\), in magnitude.

Unless otherwise defined in the instruction description, an underflow exception occurs as follows:

- **Enabled:**
  - When the tininess condition is recognized.
- **Disabled:**
  - When the tininess condition is recognized and when the delivered result value differs from what would have been computed were both the precision and the exponent range unbounded.

#### Action

The action to be taken depends on the setting of the Underflow Exception Enable bit of the FPSCR.

When Underflow Exception is enabled (FPSCR\textsubscript{UE}=1) and underflow occurs, the following actions are taken:

1. Underflow Exception is set
   \( \text{FPSCR}_{UX} \leftarrow 1 \)
2. The infinitely precise result is multiplied by \(10^\alpha\). That is, the exponent adjustment \(\alpha\) is added to the exponent. This is called the \emph{wrapped result}. The exponent adjustment for all operations, except for \emph{Round To DFP Short} and \emph{Round To DFP Long}, is 576 for DFP Long and 9216 for DFP Extended. For \emph{Round To DFP Short} and \emph{Round To DFP Long}, the exponent adjustment is 192 for the source format of DFP Long and 3072 for the source format of DFP Extended.
3. The wrapped result is rounded to the target-format precision. This is called the \emph{wrapped rounded result}.
4. If the wrapped rounded result has only one form, it is the delivered result. If the wrapped rounded result has redundant forms and is exact, the result of the form that has the exponent closest to the

wrapped ideal exponent is returned. If the wrapped rounded result has redundant forms and is inexact, the result of the form that has the smallest exponent is returned. The wrapped ideal exponent is the result of adding the exponent adjustment to the ideal exponent.

5. FPSCR<sub>FPRF</sub> is set to indicate the class and sign of the result (± Normal number)

When Underflow Exception is disabled (FPSCR<sub>UE</sub>=0) and underflow occurs, the following actions are taken:

1. Underflow Exception is set
   \[ \text{FPSCR}_{UX} \leftarrow 1 \]
2. The infinitely precise result is rounded to the target-format precision.
3. The rounded result is returned. If this result has redundant forms, the result of the form that is closest to the ideal exponent is returned.
4. FPSCR<sub>FPRF</sub> is set to indicate the class and sign of the result (± Normal number, ± Subnormal Number, or ± Zero)

### 6.5.10.5 Inexact Exception

**Definition**

Except for *Round to FP Integer Without Inexact*, the following describes the handling of the IEEE inexact exception condition. The *Round to FP Integer Without Inexact* does not recognize an inexact exception condition.

An Inexact Exception occurs when either of two conditions occur during rounding:

1. The delivered result differs from what would have been computed were both the precision and exponent range unbounded.
2. The rounded result overflows and Overflow Exception is disabled.

**Action**

The action to be taken does not depend on the setting of the Inexact Exception Enable bit of the FPSCR.

When Inexact Exception occurs, the following actions are taken:

1. Inexact Exception is set
   \[ \text{FPSCR}_{WX} \leftarrow 1 \]
2. The rounded or overflowed result is placed into the target FPR
3. FPSCR<sub>FPRF</sub> is set to indicate the class and sign of the result

**Programming Note**

In some implementations, enabling Inexact Exceptions may degrade performance more than does enabling other types of floating-point exception.
6.5.11 Summary of Normal Rounding And Range Actions

Figure 89 and Figure 90 summarize rounding and range actions, with the following exceptions:

- The Reround operation recognizes neither an underflow nor an overflow exception.
- The Round to FP Integer Without Inexact operation does not recognize the inexact operation exception.

<table>

</tbody>
</table>

Explanation:

- This situation cannot occur.
- The normal result r is considered to have been incremented.
- The rounded value, in the extreme case, may be Nmin. In this case, the exception conditions are underflow, inexact, and incremented.
- The value derived when the precise result v is rounded to the destination's precision, including both bounded precision and bounded exponent range.
- The value derived when the precise result v is rounded to the destination's precision, but assuming an unbounded exponent range.
- This is the returned value when neither overflow nor underflow is enabled.
- Precise result before rounding, assuming unbounded precision and an unbounded exponent range. For data-format conversion operations, v is the source value.
- Smallest (in magnitude) representable subnormal number in the target format.
- The result r of the exact-zero-difference case applies only to ADD and SUBTRACT with both source operands having opposite signs. (For ADD and SUBTRACT, when both source operands have the same sign, the sign of the zero result is the same sign as the sign of the source operands.)
- Largest (in magnitude) representable finite number in the target format.
- Smallest (in magnitude) representable normalized number in the target format.
- Round away from 0.
- Round to Prepare for Shorter Precision.
- Round to Nearest, Ties away from 0.
- Round to Nearest, Ties to even.
- Round toward +∞.
- Round toward −∞.
- Round toward 0.

Figure 89. Rounding and Range Actions (Part 1)

| Tiny       | Yes                | —    | —    | —    | Yes                          | —                  | —                    | Ox                               |

Explained:
— The results do not depend on this condition.
1 This condition is true by virtue of the state of some condition to the left of this column.
Round sets only the FI and FR status flags. Setting of the OX, XX, or UX flag is part of the exception actions. They are listed here for reference.

\( \beta \) Wrap adjust, which depends on the type of operation and operand format. For all operations except Round to DFP Short and Round to DFP Long, the wrap adjust depends on the target format: \( \beta = 10^\kappa \), where \( \kappa \) is 576 for DFP Long, and 9216 for DFP Extended. For Round to DFP Short and Round to DFP Long, the wrap adjust depends on the source format: \( \beta = 10^\kappa \) where \( \kappa \) is 192 for DFP Long and 3072 for DFP Extended.

\( q \) The value derived when the precise result \( v \) is rounded to destination's precision, but assuming an unbounded exponent range.

\( r \) The result as defined in Part 1 of this figure.

\( \nu \) Precise result before rounding, assuming unbounded precision and unbounded exponent range.

FI Floating-Point-Fraction-Inexact status flag, FPSCR\(_{FI}\). This status flag is non-sticky.

FR Floating-Point-Fraction-Rounded status flag, FPSCR\(_{FR}\).

OX Floating-Point Overflow Exception status flag, FPSCR\(_{UX}\).

TU The system floating-point enabled exception error handler is invoked for the overflow exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode.

TX The system floating-point enabled exception error handler is invoked for the underflow exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode.

T(x) The value \( x \) is placed at the target operand location.

Tw(x) The wrapped rounded result \( x \) is placed at the target operand location. For all operations except data format conversions, the wrapped rounded result is in the same format and length as normal results at the target location. For data format conversions, the wrapped rounded result is in the same format and length as the source, but rounded to the target-format precision.

UX Floating-Point-Underflow-Exception status flag, FPSCR\(_{UX}\).

XX Float-Point-Inexact-Exception Status flag, FPSCR\(_{XX}\). The flag is a sticky version of FPSCR\(_{FI}\). When FPSCR\(_{FI}\) is set to a new value, the new value of FPSCR\(_{XX}\) is set to the result of ORing the old value of FPSCR\(_{XX}\) with the new value of FPSCR\(_{FI}\).

Figure 90. Rounding and Range Actions (Part 2)
6.6 DFP Instruction Descriptions

The following sections describe the DFP instructions. When a 128-bit operand is used, it is held in a FPR pair and the instruction mnemonic uses a letter “q” to mean the quad-precision operation. Note that in the following descriptions, FPXp denotes a FPR pair and must address an even-odd pair. If the FPXp field specifies an odd-numbered register, then the instruction form is invalid. The notation FPX[p] means either a FPR, FPX, or a FPR pair, FPXp.

For DFP instructions, if a DFP operand is returned, the trailing significand field of the target operand is encoded using preferred DPD codes.
6.6.1 DFP Arithmetic Instructions

All DFP arithmetic instructions are X-form instructions. They all set the FI and FR status flags, and also set the FPSCR\textsubscript{FPRF} field. Furthermore, they all have an ideal exponent assigned and employ the record bit (Rc).

The arithmetic instructions consist of Add, Divide, Multiply, and Subtract.

### DFP Add [Quad] X-form

- dadd: FRT, FRA, FRB (Rc=0)
- dadd: FRT, FRA, FRB (Rc=1)
- daddq: FRTp, FRAp, FRBp (Rc=0)
- daddq: FRTp, FRAp, FRBp (Rc=1)

<table>
<thead>
<tr>
<th>59</th>
<th>FRT</th>
<th>FRA</th>
<th>FRB</th>
<th>2</th>
<th>Rc</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>31</td>
</tr>
</tbody>
</table>

The DFP operand in FRB[p] is added to the DFP operand in FRA[p].

The result is rounded to the target-format precision under control of the DRN (bits 29:31) of the FPSCR. An appropriate form of the rounded result is selected based on the ideal exponent and is placed in FRT[p]. The ideal exponent is the smaller exponent of the two source operands.

Figure 91 summarizes the actions for Add. Figure 91 does not include the setting of the FPSCR\textsubscript{FPRF} field. The FPSCR\textsubscript{FPRF} field is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

**Special Registers Altered:**
- FPRF
- FR
- FI
- FX
- OX
- UX
- XX
- VXSNAN
- VXISI
- CR1 (if Rc=1)

### DFP Subtract [Quad] X-form

- dsub: FRT, FRA, FRB (Rc=0)
- dsub: FRT, FRA, FRB (Rc=1)
- dsubq: FRTp, FRAp, FRBp (Rc=0)
- dsubq: FRTp, FRAp, FRBp (Rc=1)

<table>
<thead>
<tr>
<th>59</th>
<th>FRT</th>
<th>FRA</th>
<th>FRB</th>
<th>514</th>
<th>Rc</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>31</td>
</tr>
</tbody>
</table>

The DFP operand in FRB[p] is subtracted from the DFP operand in FRA[p].

The result is rounded to the target-format precision under control of the DRN (bits 29:31) of the FPSCR. An appropriate form of the rounded result is selected based on the ideal exponent and is placed in FRT[p]. The ideal exponent is the smaller exponent of the two source operands.

The execution of Subtract is identical to that of Add, except that the operand in FRB participates in the operation with its sign bit inverted. See Figure 91. The table does not include the setting of the FPSCR\textsubscript{FPRF} field. The FPSCR\textsubscript{FPRF} field is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

**Special Registers Altered:**
- FPRF
- FR
- FI
- FX
- OX
- UX
- XX
- VXSNAN
- VXISI
- CR1 (if Rc=1)

<td>V\text{XSNAN}: U(a)</td>
<td>V\text{XSNAN}: U(a)</td>
<td>V\text{XSNAN}: U(a)</td>
</tr>
</tbody>
</table>

**Explanation:**

- $a + b$ The value $a$ added to $b$, rounded to the target-format precision and returned in the appropriate form. (See Section 6.5.11 on page 286)
- $+dINF$ Default plus infinity.
- $-dINF$ Default minus infinity.
- $dNaN$ Default quiet NaN.
- F All finite numbers, including zeros.
- P(x) The QNaN of operand $x$ is propagated and placed in FRT[p].
- S(x) The value $x$ is placed in FRT[p] with the sign set by the rules of algebra. When the source operands have the same sign, the sign of the result is the same as the sign of the operands, including the case when the result is zero. When the operands have opposite signs, the sign of a zero result is positive in all rounding modes, except round toward $-\infty$, in which case, the sign is minus.
- T(x) The value $x$ is placed in FRT[p].
- U(x) The SNaN of operand $x$ is converted to the corresponding QNaN and placed in FRT[p].
- V\text{XISI} The Invalid-Operation Exception (VXISI) occurs. The result is produced only when the exception is disabled. (See Section 6.5.10.1 “Invalid Operation Exception” on page 282 for the exception actions.)
- V\text{XSNAN} The Invalid-Operation Exception (VXSNAN) occurs. The result is produced only when the exception is disabled. (See Section 6.5.10.1 “Invalid Operation Exception” on page 282 for the exception actions.)
**DFP Multiply [Quad]**

<table>

</tr>
</tbody>
</table>

The DFP operand in FRA[p] is multiplied by the DFP operand in FRB[p].

The result is rounded to the target-format precision under control of the DRN (bits 29:31) of the FPSCR. An appropriate form of the rounded result is selected based on the ideal exponent and is placed in FRT[p]. The ideal exponent is the sum of the two exponents of the source operands.

Figure 92 summarizes the actions for Multiply.

Figure 92 does not include the setting of the FPSCR\_FPRF field. The FPSCR\_FPRF field is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

</tr>
</tbody>
</table>

The DFP operand in FRA[p] is divided by the DFP operand in FRB[p].

The result is rounded to the target-format precision under control of the DRN (bits 29:31) of the FPSCR. An appropriate form of the rounded result is selected based on the ideal exponent and is placed in FRT[p]. The ideal exponent is the difference of subtracting the exponent of the divisor from the exponent of the dividend.

**Figure 93 summarizes the actions for Divide.** Figure 93 does not include the setting of the FPSCR FPRF field. The FPSCR FPRF field is always set to the class and sign of the result, except for an enabled invalid-operation and enabled zero-divide exceptions, in which cases the field remains unchanged.

**Special Registers Altered:**
- FPRF FR FI
- FX OX UX ZK XX
- VXSNAN VXIDI VXZDZ CR1

**Operand a in FRA[p] is**

| Actions for Divide (a ÷ b) when operand b in FRB[p] is |
|------------|----------|----------|----------|----------|
| 0 | Fn | ∞ | QNaN | SNaN |

- *VXZD*: T(dNaN) S(a ÷ b) S(zt) P(b) VXSNAN: U(b)
- *VXID*: T(dNaN) S(a ÷ b) S(zt) P(b) VXSNAN: U(b)
- *VXIDI*: P(a) P(a) P(a) P(a) VXSNAN: U(b)
- *VXSNAN*: V(a) V(a) V(a) V(a) V(a)

**Explanation:**
- a ÷ b The value a divided by b, rounded to the target-format precision and returned in the appropriate form. (See Section 6.5.11 on page 286.)
- dINF Default infinity.
- dNaN Default quiet NaN.
- Fn Finite nonzero number (includes both normal and subnormal numbers).
- P(x) The QNaN of operand x is propagated and placed in FRT[p].
- S(x) The value x is placed in FRT[p] with the sign set to the exclusive-OR of the source-operand signs.
- T(x) The value x is placed in FRT[p].
- U(x) The SNaN of operand x is converted to the corresponding QNaN and placed in FRT[p].
- VXIDI: The Invalid-Operation Exception (VXIDI) occurs. The result is produced only when the exception is disabled. (See Section 6.5.10.1 “Invalid Operation Exception” on page 282 for the exception actions.)
- VXSNAN: The Invalid-Operation Exception (VXSNAN) occurs. The result is produced only when the exception is disabled. (See Section 6.5.10.1 “Invalid Operation Exception” on page 282 for the exception actions.)
- VXZD: The Invalid-Operation Exception (VXZD) occurs. The result is produced only when the exception is disabled. (See Section 6.5.10.1 “Invalid Operation Exception” on page 282 for the exception actions.)
- zt True zero (zero significand and most negative exponent).
- Zx The Zero-Divide Exception occurs. The result is produced only when the exception is disabled. (See Section 6.5.10.2 “Zero Divide Exception” on page 283 for the exception actions.)
6.6.2 DFP Compare Instructions

The DFP compare instructions consist of the *Compare Ordered* and *Compare Unordered* instructions. The compare instructions do not provide the record bit.

The comparison sets the designated CR field to indicate the result. The FPSCR\textsubscript{FPCC} is set in the same way.

The codes in the CR field BF and FPSCR\textsubscript{FPCC} are defined for the DFP compare operations as follows:

<table>
<thead>
<tr>
<th>Bit Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>FL (FRA[p]) &lt; (FRB[p])</td>
</tr>
<tr>
<td>1</td>
<td>FG (FRA[p]) &gt; (FRB[p])</td>
</tr>
<tr>
<td>2</td>
<td>FE (FRA[p]) = (FRB[p])</td>
</tr>
<tr>
<td>3</td>
<td>FU (FRA[p]) ? (FRB[p])</td>
</tr>
</tbody>
</table>

<td>k ≠ 0 and k &gt; NSDb, or k = 0</td>
</tr>
</tbody>
</table>

Figure 97. Actions: Test Significance
6.6.4 DFP Quantum Adjustment Instructions

The Quantum Adjustment operations consist of the Quantize, Quantize Immediate, Reround, and Round To FP Integer operations.

The Quantum Adjustment instructions are Z23-form instructions and have an immediate RMC (Rounding-Mode-Control) field, which specifies the rounding mode used. For Quantize, Quantize Immediate, and Reround, the RMC field contains the primary encoding. For Round To FP Integer, the field contains either primary or secondary encoding, depending on the setting of a RMC-encoding-selection bit. See Section 6.5.2 “Rounding Mode Specification” on page 277 for the definition of RMC encoding.

All Quantum Adjustment instructions set the FI and FR status flags, and also set the FPSCR_FPRF field. The record bit is provided to each of these instructions. They return the target operand in a form with the ideal exponent.

DFP Quantize Immediate [Quad] Z23-form

\[
\begin{array}{cccccc}
59 & FRT & TE & FRB & RMC & 67 \\
0 & 6 & 11 & 16 & 21 & 23 \\
\end{array}
\]

\[
\begin{array}{cccccc}
63 & FRTp & TE & FRBp & RMC & 67 \\
0 & 6 & 11 & 16 & 21 & 23 \\
\end{array}
\]

The DFP operand in FRB[p] is converted and rounded to the form with the exponent specified by TE based on the rounding mode specified in the RMC field. TE is a 5-bit signed binary integer. The result of that form is placed in FRT[p]. The sign of the result is the same as the sign of the operand in FRB[p]. The ideal exponent is the exponent specified by TE.

When the value of the operand in FRB[p] is greater than \((10^p-1) \times 10^{TE}\), where \(p\) is the format precision, an invalid operation exception is recognized.

When the delivered result differs in value from the operand in FRB[p], an inexact exception is recognized. No underflow exception is recognized by this operation, regardless of the value of the operand in FRB[p].

The FPSCR_FPRF field is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

Special Registers Altered:

- FPRF
- FR
- FI
- FX
- VXSNAN
- VXCVI
- CR1 (if Rc=1)

Programming Note

DFP Quantize Immediate can be used to adjust values to a form having the specified exponent in the range -16 to 15. If the adjustment requires the significand to be shifted left, then:

- if the result would cause overflow from the most significant digit, the result is a default QNaN.;
- otherwise the result is the adjusted value (left shifted with matching exponent).

If the adjustment requires the significand to be shifted right, the result is rounded based on the value of the RMC field.

DFP Quantize Immediate can round a value to a specific number of fractional digits. Consider the computation of sales tax. Values expressed in U.S. dollars have 2 fractional digits, and sales tax rates typically have 3 fractional digits. The product of value and rate will yield 5 fractional digits. For example:

\[
39.95 \times 0.075 = 2.99625
\]

This result needs to be rounded to the penny to compute the correct tax of $3.00.

The following sequence computes the sales tax assuming the pre-tax total is in FRA and the tax rate is in FRB. The DFP Quantize Immediate instruction rounds the product (FRA * FRB) to 2 fractional digits (TE field = -2) using Round to nearest, ties away from 0 (RMC field = 2). The quantized and rounded result is placed in FRT.

\[
dmul \\ dquai -2,FRT,f0,2
\]
**DFP Quantize [Quad]**

The DFP operand in register FRB[p] is converted and rounded to the form with the same exponent as that of the DFP operand in FRA[p] based on the rounding mode specified in the RMC field. The result of that form is placed in FRT[p]. The sign of the result is the same as the sign of the operand in FRB[p]. The ideal exponent is the exponent specified in FRA[p].

When the value of the operand in FRB[p] is greater than \((10^p-1) \times 10^{E_a}\), where \(p\) is the format precision and \(E_a\) is the exponent of the operand in FRA[p], an invalid operation exception is recognized.

When the delivered result differs in value from the operand in FRB[p], an inexact exception is recognized. No underflow exception is recognized by this operation, regardless of the value of the operand in FRB[p].

Figure 99 and Figure 100 summarize the actions. The tables do not include the setting of the FPSCR\textsubscript{FRF} field. The FPSCR\textsubscript{FRF} field is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

---

**Special Register Altered:**

<table>
<thead>
<tr>
<th></th>
<th>FPRF</th>
<th>FR</th>
<th>FI</th>
</tr>
</thead>
<tbody>

<td></td>
<td></td>
</tr>
<tr>
<td>CR1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**(if Rc=1)**

---

**Programming Note**

**DFP Quantize** can be used to adjust one DFP value (FRB[p]) to a form having the same exponent as a second DFP value (FRA[p]). If the adjustment requires the significand to be shifted left, then:

- if the result would cause overflow from the most significant digit, the result is a default QNaN;
- otherwise the result is the adjusted value (left shifted with matching exponent).

If the adjustment requires the significand to be shifted right, the result is rounded based on the value of the RMC field. Figure 98 shows examples of these adjustments.

</tr>
</tbody>
</table>

Let k be the contents of bits 58:63 of FRA that specifies the reference significance.

When the DFP operand in FRB[p] is a finite number, and if the reference significance is zero, or if the reference significance is nonzero and the number of significant digits of the source operand is less than or equal to the reference significance, then the value and the form of the source operand is placed in FRT[p]. If the reference significance is nonzero and the number of significant digits of the source operand is greater than the reference significance, then the source operand is converted and rounded to the number of significant digits specified in the reference significance based on the rounding mode specified in the RMC field. The result of the form with the specified number of significant digits is placed in FRT[p]. The sign of the result is the same as the sign of the operand in FRB[p].

For this instruction, the number of significant digits of the value 0 is considered to be zero. The ideal exponent is the greater value of the exponent of the operand in FRB[p] and the referenced exponent. The referenced exponent is the resultant exponent if the operand in FRB[p] would have been converted and rounded to the number of significant digits specified in the reference significance based on the rounding mode specified in the RMC field.

If the exponent of the rounded result of the form that has the specified number of significant digits would be greater than $X_{\text{max}}$, an invalid operation exception (VXCVI) occurs. When the invalid-operation exception occurs, and if the exception is disabled, a default QNaN is returned. When an invalid-operation exception occurs, no inexact exception is recognized.

In the absence of an invalid-operation exception, if the result differs in value from the operand in FRB[p], an inexact exception is recognized.

This operation causes neither an overflow nor an underflow exception.

Figure 102 summarizes the actions for Reround. The table does not include the setting of the FPSR<sub>FPFR</sub> field. The FPSR<sub>FPFR</sub> field is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

Special Registers Altered:
- FPRF
- FR
- FI
- FX
- XX
- VXSNAN
- VXCVI
- CR1 (if Rc=1)

Programming Note

DFP Reround can be used to adjust a DFP value (FRB[p]) to have no more than a specified number (FRA[p]58:63) of significant digits. The result (FRT[p]) is right-justified leaving the specified number of digits and rounded as specified by the RMC field. If rounding increases the number of significant digits, the result is adjusted again (the significand is shifted right 1 digit and the exponent is incremented by 1). Figure 101 has example results from DFP Reround for 1, 2, and 10 significant digits.

Programming Note

DFP Reround is primarily used to round a DFP value to a specific number of digits before conversion to string format for printing or display. Another use for DFP Reround is to obtain the effective exponent of the most significant digit by specifying a reference significance of 1. The exponent can be extracted and used to compute the number of significant digits or to left-justify a value.

For example, the following sequence computes the number of significant digits and returns it as an integer. FRB is the DFP value for which we want the number of significant digits; f13 contains the reference significance value 0x0000000000000001; and r1 is the stack pointer, with free space for doublewords at offsets -8 and -16. These doublewords are used to transfer the biased exponents from the FPRs to GPRs for integer computation. R3 contains the result of $E(\text{reround}(1,FRA)) - E(FRA) + 1$, where $E(x)$ represents the biased exponent of x.

```
dxex  f0,FRB
stfd  f0,-16(r1)
drrnd  f1,f13,FRB,1  # reround 1 digit toward 0
dxex  f1,f1
stfd  f1,-8(r1)
lfd  r11,-16(r1)
lfd  r3,-8(r1)
subf  r3,r11,r3
addi  r3,r3,1
```

Given the value 412.34 the result is $E(4 \times 102) - E(41234 \times 10-2) + 1 = (398+2) - (398-2) + 1 = 400 - 396 + 1 = 5$. Additional code is required to detect and handle special values like Subnormal, Infinity, and NaN.
### Programming Note

*DFP Reround* combined with *DFP Quantize* can be used to left justify a value (as needed by the frexp function). FRB is the DFP value for which we want to left justify; f13 contains the reference significance value 0x0000000000000001; and r1 is the stack pointer, with free space for a doubleword at offset -8. This doubleword is used to transfer the biased exponents from the FPR to a GPR, for integer computation. The adjusted biased exponent (+ format precision - 1) is transferred back into an FPR so it can be inserted into the rerounded value. The adjusted rerounded value becomes the quantize reference value. The quantize instruction returns the left justified result in FRT.

```
drrmd f1, f13, FRB, 1 # reround 1 digit toward 0
dxex f0, f1
stfd f0, -8(r1)
ldr r1l, -8(r1)
addi r1l, r1l, 15 # biased exp + precision - 1
ldr r1l, -8(r1)
stfd f0, -8(r1)
diex f1, f0, f1 # adjust exponent
dqua FRT, f1, f0, 1 # quantize to adjusted exponent
```
### Actions for Reround when operand b in FRB[p] is

<table>
<thead>
<tr>
<th>Condition</th>
<th>0*</th>
<th>Fn</th>
<th>∞</th>
<th>QNaN</th>
<th>SNaN</th>
</tr>
</thead>
<tbody>

<td>W(b)</td>
<td>T(dINF)</td>
<td>P(b)</td>
<td>V_{XSNAN}; U(b)</td>
</tr>
</tbody>
</table>

**Explanation:**
- * The number of significant digits of the value 0 is considered to be zero for this instruction.
- - Not applicable.
- dINF Default infinity.
- Fn Finite nonzero numbers (includes both subnormal and normal numbers).
- k Reference significance, which specifies the number of significant digits in the target operand.
- m Number of significant digits in the operand in FRB[p].
- P(x) The QNaN of operand x is propagated and placed in FRT[p].
- RR(x) The value x is rounded to the form that has the specified number of significant digits.
  - If RR(x) \( \leq (10^{k-1}) \times 10^{\lambda_{\text{max}}} \), then RR(x) is returned; otherwise an invalid-operation exception is recognized.
- T(x) The value x is placed in FRT[p].
- U(x) The SNaN of operand x is converted to the corresponding QNaN and placed in FRT[p].
- V_{XCVI} The Invalid-Operation Exception (VXCVI) occurs. The result is produced only when the exception is disabled. (See Section 6.5.10.1 for actions.)
- V_{XSNAN} The Invalid-Operation Exception (VXSNAN) occurs. The result is produced only when the exception is disabled. See Section 6.5.10.1 for actions.
- W(x) The value and the form of x is placed in FRT[p].

**Figure 102.** Actions: Reround
**DFP Round To FP Integer With Inexact [Quad]**

The DFP operand in FRB[p] is rounded to a floating-point integer and placed into FRT[p]. The sign of the result is the same as the sign of the operand in FRB[p]. The ideal exponent is the larger value of zero and the exponent of the operand in FRB[p].

The rounding mode used is specified in the RMC field. When the RMC-encoding-selection (R) bit is zero, the RMC field contains the primary encoding; when the bit is one, the field contains the secondary encoding.

In addition to coercion of the converted value to fit the target format, the special rounding used by Round To FP Integer also coerces the target exponent to the ideal exponent.

When the operand in FRB[p] is a finite number and the exponent is less than zero, the operand is rounded to the result with an exponent of zero. When the exponent is greater than or equal to zero, the result is set to the numerical value and the form of the operand in FRB[p].

When the result differs in value from the operand in FRB[p], an inexact exception is recognized. No underflow exception is recognized by this operation, regardless of the value of the operand in FRB[p].

Figure 103 summarizes the actions for Round To FP Integer With Inexact. The table does not include the setting of the FPSCR_FPRF field. The FPSCR_FPRF field is always set to the class and sign of the result, except for an enabled invalid-operation, in which case the field remains unchanged.

**Special Registers Altered:**
- FPRF
- FR
- FI
- FX
- VXSNAN
- CR1 (if R=1)

---

**Programming Note**

The DFP Round To FP Integer With Inexact and DFP Round To FP Integer With Inexact Quad instructions can be used to implement the decimal equivalent of the C99 rint function by specifying the primary RMC encoding for round according to FPSCR_DIR (R=0, RMC=11). The specification for rint requires the inexact exception be raised if detected.

</tbody>
</table>

Explanation:

* Setting of XX and VXSNAN is part of the corresponding exception actions. Also, when an invalid-operation exception occurs, setting of FI and FR is part of the exception actions. (See the sections, “Inexact Exception” and “Invalid Operation Exception” for more details.)

- The actions do not depend on this condition.

1 This condition is true by virtue of the state of some condition to the left of this column.

dINF Default infinity.

F All finite numbers, including zeros.

FI Floating-Point-Fraction-Inexact status flag, FPSCR\(_{FI}\).

FR Floating-Point-Fraction-Rounded status flag, FPSCR\(_{FR}\).

n The value derived when the source operand, b, is rounded to an integer using the special rounding for Round To FP Integer.

P(x) The QNaN of operand x is propagated and placed in FRT\([p]\).

T(x) The value x is placed in FRT\([p]\).

TV The system floating-point enabled exception error handler is invoked for the invalid-operation exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode.

TX The system floating-point enabled exception error handler is invoked for the inexact exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode.

U(x) The SNaN of operand x is converted to the corresponding QNaN and placed in FPT\([p]\).

W(x) The value x in the form of zero exponent or the source exponent is placed in FRT\([p]\).

XX Floating-Point-Inexact-Exception status flag, FPSCR\(_{XX}\).

<td></td>
</tr>
</tbody>
</table>

This operation is the same as the *Round To FP Integer With Inexact* operation, except that this operation does not recognize an inexact exception.

Figure 104 summarizes the actions for *Round To FP Integer Without Inexact*. The table does not include the setting of the FPSCR[RPF] field. The FPSCR[RPF] field is always set to the class and sign of the result, except for an enabled invalid-operation, in which case the field remains unchanged.

Special Registers Altered:
- FPRF FR (set to 0) FI (set to 0)
- FX
- VXSNAN
- CR1

**Programming Note**
The *DFP Round To FP Integer Without Inexact* and *DFP Round To FP Integer Without Inexact Quad* instructions can be used to implement decimal equivalents of several C99 rounding functions by specifying the appropriate R and RMC field values.

### Function

<table>
<thead>
<tr>
<th>Function</th>
<th>R</th>
<th>RMC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ceil</td>
<td>1</td>
<td>0b00</td>

- U(x) The SNaN of operand x is converted to the corresponding QNaN and placed in FPT[p].
- W(x) The value x in the form of zero exponent or the source exponent is placed in FRT[p].

**Figure 104. Actions: Round to FP Integer Without Inexact**
6.6.5 DFP Conversion Instructions

The DFP conversion instructions consist of data-format conversion instructions and data-type conversion instructions. They are all X-form instructions and employ the record bit (Rc).

6.6.5.1 DFP Data-Format Conversion Instructions

The data-format conversion instructions consist of Convert To DFP Long, Convert To DFP Extended, Round To DFP Short, and Round To DFP Long. Figure 105 summarizes the actions for these instructions.

--- Programming Note ---

DFP does not provide operations on short operands, so they must be converted to long format, and then converted back to be stored. Preserving correct signaling NaN semantics requires that signaling NaNs be propagated from the source to the result without recognizing an exception during widening from short to long or narrowing from long to short. Because DFP does not provide equivalents to the FP Load Floating-Point Single and Store Floating-Point Single functions, the widening is performed by loading the DFP short value with a Load Floating as Integer Word Indexed followed by a DFP Convert to DFP Long, and narrowing is performed by a DFP Round to DFP Short followed by a Store Floating-Point as Integer Word Indexed. If the SNaN or infinity in DFP short format uses the preferred DPD encoding, then converting this operand to DFP long format and back to DFP short will result in the original bit pattern.

--- Programming Note ---

DFP does not provide operations on short operands, so they must be converted to long format, and then converted back to be stored. Preserving correct signaling NaN semantics requires that signaling NaNs be propagated from the source to the result without recognizing an exception during widening from short to long or narrowing from long to short. Because DFP does not provide equivalents to the FP Load Floating-Point Single and Store Floating-Point Single functions, the widening is performed by loading the DFP short value with a Load Floating as Integer Word Indexed followed by a DFP Convert to DFP Long, and narrowing is performed by a DFP Round to DFP Short followed by a Store Floating-Point as Integer Word Indexed. If the SNaN or infinity in DFP short format uses the preferred DPD encoding, then converting this operand to DFP long format and back to DFP short will result in the original bit pattern.

--- Programming Note ---

DFP does not provide operations on short operands, so they must be converted to long format, and then converted back to be stored. Preserving correct signaling NaN semantics requires that signaling NaNs be propagated from the source to the result without recognizing an exception during widening from short to long or narrowing from long to short. ### DFP Convert To DFP Long  

<table>
<thead>
<tr>
<th>X-form</th>
<th>DCTDP</th>
<th>FRT,FRB</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>dctdp</td>
<td>(Rc=0)</td>
</tr>
<tr>
<td></td>
<td>dctdp.</td>
<td>(Rc=1)</td>
</tr>
</tbody>
</table>

The DFP short operand in bits 32:63 of FRB is converted to DFP long format and the converted result is placed into FRT. The sign of the result is the same as the sign of the source operand. The ideal exponent is the exponent of the source operand.

If the operand in FRB is an SNaN, it is converted to an SNaN in DFP long format and does not cause an invalid-operation exception.

**Special Registers Altered:**
- FPRF FR (undefined)
- FI (undefined)
- CR1 (if Rc=1)

**Programming Note**

Note that DFP short format is a storage-only format. Therefore, conversion of a short SNaN to long format will not cause an exception and the SNaN is preserved. Subsequent operation on that SNaN in long format will cause an exception.

### DFP Convert To DFP Extended  

<table>
<thead>
<tr>
<th>X-form</th>
<th>DCTQPQ</th>
<th>FRTp,FRB</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>dctqpq</td>
<td>(Rc=0)</td>
</tr>
<tr>
<td></td>
<td>dctqpq.</td>
<td>(Rc=1)</td>
</tr>
</tbody>
</table>

The DFP long operand in the FRB is converted to DFP extended format and placed into FRTp. The sign of the result is the same as the sign of the operand in FRB. The ideal exponent is the exponent of the operand in FRB.

If the operand in FRB is an SNaN, an invalid-operation exception is recognized. If the exception is disabled, the SNaN is converted to the corresponding QNaN in DFP extended format.

**Special Registers Altered:**
- FPRF FR (set to 0)
- FI (set to 0)
- CR1 (if Rc=1)
- FX
- VXSNAN
**DFP Round To DFP Short**  
**X-form**

<table>
<thead>
<tr>
<th>drsp</th>
<th>FRT,FRB</th>
<th>(Rc=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>drsp.</td>
<td>FRT,FRB</td>
<td>(Rc=1)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>59</th>
<th>FRT</th>
<th>FRB</th>
<th>770</th>
<th>Rc</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

The DFP long operand in FRB is converted and rounded to DFP short format. The DFP short value is extended on the left with zeros to form a 64-bit entity and placed into FRT. The sign of the result is the same as the sign of the source operand. The ideal exponent is the exponent of the source operand.

If the operand in FRB is an SNaN, it is converted to an SNaN in DFP short format and does not cause an invalid-operation exception.

Normally, the result is in the format and length of the target. However, when an overflow or underflow exception occurs and if the exception is enabled, the operation is completed by producing a wrapped rounded result in the same format and length as the source but rounded to the target-format precision.

**Special Registers Altered:**
- FPRF
- FR
- FI
- FX
- OX
- UX
- XX
- CR1 (if Rc=1)

**Programming Note**

Note that DFP short format is a storage-only format. Therefore, conversion of a long SNaN to short format will not cause an exception. Converting a long format SNaN to short format is an implied move operation.

</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

The DFP extended operand in FRBp is converted and rounded to DFP long format. The result concatenated with 64 0s is placed in FRTp. The sign of the result is the same as the sign of the source operand. The ideal exponent is the exponent of the operand in FRBp.

If the operand in FRBp is an SNaN, an invalid-operation exception is recognized. If the exception is disabled, the SNaN is converted to the corresponding QNaN in DFP long format.

Normally, the result is in the format and length of the target. However, when an overflow or underflow exception occurs and if the exception is enabled, the operation is completed by producing a wrapped rounded result in the same format and length as the source but rounded to the target-format precision.

**Special Registers Altered:**
- FPRF
- FR
- FI
- FX
- OX
- UX
- XX
- VXSNAN
- CR1 (if Rc=1)

**Programming Note**

Note that DFP Round to DFP Long, while producing a result in DFP long format, actually targets a register pair, writing 64 0s in FRTp+1.
6.6.5.2 DFP Data-Type Conversion Instructions

The DFP data-type conversion instructions are used to convert data type between DFP and fixed.

### DFP Convert From Fixed

<table>

</tr>
</tbody>
</table>

The 64-bit signed binary integer in FRB is converted and rounded to a DFP Long value and placed into FRT. The sign of the result is the same as the sign of the source operand. The ideal exponent is zero.

If the source operand is a zero, then a plus zero with a zero exponent is returned.

The FPSCR_FPRF field is set to the class and sign of the result.

**Special Registers Altered:**
- FPRF FR FI
- FX XX
- CR1 (if Rc=1)

The DFP operand in FRB[p] is rounded to an integer value and is placed into FRT in the 64-bit signed binary integer format. The sign of the result is the same as the sign of the source operand, except when the source operand is a NaN or a zero.

The FPSCR_FPRF field is set to the class and sign of the result.

**Special Registers Altered:**
- FPRF (undefined) FR FI
- VXSNAN VXCVI
- CR1 (if Rc=1)

### Programming Note

It is recommended that software pre-round the operand to a floating-point integral using `drintx[q]` or `drintn[q]` is a rounding mode other than the current rounding mode specified by FPSCR_DRN is needed. Saving, modifying and restoring the FPSCR just to temporarily change the rounding mode is less efficient than just employing drint[p] or drint[p] which override the current rounding mode using an immediate control field.

For example if the desired function rounding is Round to Nearest, Ties away from 0 but the default rounding (from FPSCR_DRN) is Round to Nearest, Ties to Even then following is preferred.

- `drintn 0, f1, f1, 2`
- `dctfix f1, f1`
| Operand $b$ in FRB[p] is | $q$ is | Is $n$ not precise \((n \neq b)\) | Inv.-Op. Except. Enabled | Inexact Except. Enabled | Is $n$ Incremented \(|n| > |b|\) | Actions * |
|--------------------------|--------|-------------------------------|-------------------|-------------------|-------------------------|-------------|
| $-\infty \leq b < MN$    | $< MN$ | -                             | No                | -                 | -                       | $T(MN), FI \leftarrow 0, FR \leftarrow 0, VXCVI \leftarrow 1$ |

Explanation:

* Setting of XX, VXCVI, and VXSNAN is part of the corresponding exception actions. Also, when an invalid-operation exception occurs, setting of FI and FR bits is part of the exception actions. (See the sections, “Inexact Exception” and “Invalid Operation Exception” for more details.)

- The actions do not depend on this condition.

| FI | Floating-Point-Fraction-Inexact status flag, FPSCRFI. |
| FR | Floating-Point-Fraction-Rounded status flag, FPSCRFR. |
| MN | Maximum negative number representable by the 64-bit binary integer format |
| MP | Maximum positive number representable by the 64-bit binary integer format |
| n  | The value $q$ converted to a fixed-point result. |
| q  | The value derived when the source value $b$ is rounded to an integer using the specified rounding mode |
| T(x) | The value $x$ is placed in FRT[p]. |
| TV | The system floating-point enabled exception error handler is invoked for the invalid-operation exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode. |
| TX | The system floating-point enabled exception error handler is invoked for the inexact exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode. |
| VXCVI | The FPSCR$_{VXCVI}$ invalid operation exception status bit. |
| VXSNAN | The FPSCR$_{VXSNAN}$ invalid operation exception status bit. |
| XX | Floating-Point-Inexact-Exception status flag, FPSCR$_{XX}$. |

Figure 106. Actions: Convert To Fixed
6.6.6 DFP Format Instructions

The DFP format instructions are used to compose or decompose a DFP operand. A source operand of SNaN does not cause an invalid-operation exception. All format instructions employ the record bit (Rc).

**DFP Decode DPD To BCD [Quad] X-form**

<table>
<thead>
<tr>
<th>ddedpd</th>
<th>SP,FRT,FRB</th>

<td>16</td>
</tr>
<tr>
<td>21</td>
<td>834</td>
</tr>
<tr>
<td>31</td>
<td>Rc</td>
</tr>
</tbody>
</table>

A portion of the significand of the DFP operand in FRB[p] is converted to a signed or unsigned BCD number depending on the SP field. For infinity and NaN, the significand is considered to be the contents in the trailing significand field padded on the left by a zero digit.

**SP0 = 0 (unsigned conversion)**

The rightmost 16 digits of the significand (32 digits for ddedpdq) is converted to an unsigned BCD number and the result is placed into FRT[p].

**SP0 = 1 (signed conversion)**

The rightmost 15 digits of the significand (31 digits for ddedpdq) is converted to a signed BCD number with the same sign as the DFP operand, and the result is placed into FRT[p]. If the DFP operand is negative, the sign is encoded as 0b1101. If the DFP operand is positive, SP1 indicates which preferred plus sign encoding is used. If SP1 = 0, the plus sign is encoded as 0b1100 (the option-1 preferred sign code), otherwise the plus sign is encoded as 0b1111 (the option-2 preferred sign code).

**Special Registers Altered:**

CR1 (if Rc=1)

The format instructions consist of Decode DPD To BCD, Encode BCD To DPD, Extract Biased Exponent, Insert Biased Exponent, Shift Significand Left Immediate, and Shift Significand Right Immediate.
### DFP Extract Biased Exponent [Quad] X-form

| dxex  | FRT,FRB | (Rc=0) |
| dxex. | FRT,FRB | (Rc=1) |

| dxexq | FRT,FRBp | (Rc=0) |
| dxexq. | FRT,FRBp | (Rc=1) |

The biased exponent of the operand in FRB[p] is extracted and placed into FRT in the 64-bit signed binary integer format. When the operand in FRB is an infinity, QNaN, or SNaN, a special code is returned.

**Operand Result**
- Finite Number: biased exponent value
- Infinity: -1
- QNaN: -2
- SNaN: -3

**Special Registers Altered:**
- CR1 (if Rc=1)

**Programming Note**
The exponent bias value is 101 for DFP Short, 398 for DFP Long, and 6176 for DFP Extended.

### DFP Insert Biased Exponent [Quad] X-form

| diex  | FRT,FRA,FRB | (Rc=0) |
| diex. | FRT,FRA,FRB | (Rc=1) |

| diexq | FRTp,FRA,FRBp | (Rc=0) |
| diexq. | FRTp,FRA,FRBp | (Rc=1) |

Let a be the value of the 64-bit signed binary integer in FRA.

- **Result**
  - \( a > \text{MBE} \): QNaN
  - \( MBE \geq a \geq 0 \): Finite number with biased exponent a
  - \( a = -1 \): Infinity
  - \( a = -2 \): QNaN
  - \( a = -3 \): SNaN
  - \( a < -3 \): QNaN

1 Maximum biased exponent for the target format

When \( 0 \leq a \leq \text{MBE} \), a is the biased target exponent that is combined with the sign bit and the significand value of the DFP operand in FRB[p] to form the DFP result in FRT[p]. The ideal exponent is the specified target exponent.

When a specifies a special code (\( a < 0 \) or \( a > \text{MBE} \)), an infinity, QNaN, or SNaN is formed in FRT[p] with the trailing significand field containing the value from the trailing significand field of the source operand in FRB[p], and with an N-bit combination field set as follows:

- For an Infinity result,
  - the leftmost 5 bits are set to 0b11110, and
  - the rightmost N-5 bits are set to zero.

- For a QNaN result,
  - the leftmost 5 bits are set to 0b11111,
  - bit 5 is set to zero, and
  - the rightmost N-5 bits are set to zero.

- For an SNaN result,
  - the leftmost 5 bits are set to 0b11111,
  - bit 5 is set to one, and
  - the rightmost N-5 bits are set to zero.

**Special Registers Altered:**
- CR1 (if Rc=1)

**Programming Note**
The exponent bias value is 101 for DFP Short, 398 for DFP Long, and 6176 for DFP Extended.
### Table: Actions for Insert Biased Exponent

<table>
<thead>
<tr>
<th>Operand a in FRA[p] specifies</th>
<th>Actions for Insert Biased Exponent when operand b in FRB[p] specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>F</td>
</tr>
<tr>
<td>F</td>
<td>N, Rb</td>
</tr>
<tr>
<td>( \infty )</td>
<td>I, Rb</td>
</tr>
<tr>
<td>QNaN</td>
<td>Q, Rb</td>
</tr>
<tr>
<td>SNaN</td>
<td>S, Rb</td>
</tr>
</tbody>
</table>

**Explanation:**

- **F**: All finite numbers, including zeros
- **I**: The combination field in FRT[p] is set to indicate a default Infinity.
- **N**: The combination field in FRT[p] is set to the specified biased exponent in FRA and the leftmost significand digit in FRB[p].
- **Q**: The combination field in FRT[p] is set to indicate a default QNaN.
- **S**: The combination field in FRT[p] is set to indicate a default SNaN.
- **Z**: The combination field in FRT[p] is set to indicate the specific biased exponent in FRA and a leftmost coefficient digit of zero.
- **Rb**: The contents of the trailing significand field in FRB[p] are reencoded using preferred DPD encodings and the reencoded result is placed in the same field in FRT[p]. The sign bit of FRB[p] is copied into the sign bit in FRT[p].

**Figure 107. Actions: Insert Biased Exponent**
DFP Shift Significand Left Immediate
[Quad] Z22-form

dscli  FRT,FRA,SH  (Rc=0)
dscli. FRT,FRA,SH  (Rc=1)
dscliq FRTp,FRAp,SH  (Rc=0)
dscliq. FRTp,FRAp,SH  (Rc=1)

The significand of the DFP operand in FRA[p] is shifted left SH digits. For a NaN or infinity, all significand digits are in the trailing significand field. SH is a 6-bit unsigned binary integer. Digits shifted out of the leftmost digit are lost. Zeros are supplied to the vacated positions on the right. The result is placed into FRT[p]. The sign of the result is the same as the sign of the source operand in FRA[p].

If the source operand in FRA[p] is a finite number, the exponent of the result is the same as the exponent of the source operand.

For an Infinity, QNaN or SNaN result, the target format's N-bit combination field is set as follows.

- For an Infinity result,
  - the leftmost 5 bits are set to 0b11110, and
  - the rightmost N-5 bits are set to zero.
- For a QNaN result,
  - the leftmost 5 bits are set to 0b11111,
  - bit 5 is set to zero, and
  - the rightmost N-6 bits are set to zero.
- For an SNaN result,
  - the leftmost 5 bits are set to 0b11111,
  - bit 5 is set to one, and
  - the rightmost N-6 bits are set to zero.

### Explanation:

1. FI and FR are set to zeros for these instructions.
2. A unique definition of the FPSCR<sub>FPCC</sub> field is provided for the instruction.
3. These are the only instructions that may generate an SNaN and also set the FPSCR<sub>FPRF</sub> field. Since the BFP FPSCR<sub>FPRF</sub> field does not include a code for SNaN, these instructions cause the need for redefining the FPSCR<sub>FPRF</sub> field for DFP.

- **DCM**: A 6-bit immediate operand specifying the data-class mask.
- **DGM**: A 6-bit immediate operand specifying the data-group mask.
- **G**: An SNaN can be generated as the target operand.
- **IE**: An ideal exponent is defined for the instruction.
- **FI**: Setting of the FPSCR<sub>F</sub> flag.
- **FR**: Setting of the FPSCR<sub>FR</sub> flag.
- **N**: No.
- **O**: An overflow exception may be recognized.
- **Rc**: The record bit, Rc, is provided to record FPSCR<sub>0:3</sub> in CR field 1.
- **RE**: The trailing significand field is reencoded using preferred DPD encodings. The preferred DPD encoding are also used for propagated NaNs, or converted NaNs and infinities.
- **RMC**: A 2-bit immediate operand specifying the rounding-mode control.
- **S**: An one-bit immediate operand specifying if the operation is signed or unsigned.
- **SP**: A two-bit immediate operand: one bit specifies if the operation is signed or unsigned and, for signed operations, another bit specifies which preferred plus sign code is generated.
- **U**: An underflow exception may be recognized.
- **V**: An invalid-operation exception may be recognized.
- **Vs**: An input operand of SNaN causes an invalid-operation exception.
- **X**: An inexact exception may be recognized.
- **Y**: Yes.
- **U**: Undefined
- **Z**: A zero-divide exception may be recognized.
Chapter 7. Vector-Scalar Floating-Point Operations [Category: VSX]

7.1 Introduction

7.1.1 Overview of the Vector-Scalar Extension

Category Vector-Scalar Extension (VSX) provides facilities supporting vector and scalar binary floating-point operations. The following VSX features are provided to increase opportunities for vectorization.

- A unified register file, a set of Vector-Scalar Registers (VSR), supporting both scalar and vector operations is provided, eliminating the overhead of vector-scalar data transfer through storage.
- Support for word-aligned storage accesses for both scalar and vector operations is provided.
- Robust support for IEEE-754 for both vector and scalar floating-point operations is provided.

Combining the Floating-Point Registers (FPR) defined in Chapter 4. Floating-Point Facility [Category: Floating-Point] and the Vector Registers (VR) defined in Chapter 5. Vector Facility [Category: Vector] provides additional registers to support more aggressive compiler optimizations for both vector and scalar operations.

Implementations of VSX must also implement the Floating-Point (Chapter 4) and Vector (Chapter 5) categories.

7.1.1.1 Compatibility with Category Floating-Point and Category Decimal Floating-Point Operations

The instruction sets defined in Chapter 4. Floating-Point Facility [Category: Floating-Point] and Chapter 6. Decimal Floating-Point [Category: Decimal Floating-Point] retain their definition with one primary difference. The FPRs are mapped to doubleword element 0 of VSRs 0-31. The contents of doubleword 1 of the VSR corresponding to a source FPR specified by an instruction are ignored. The contents of doubleword 1 of a VSR corresponding to the target FPR specified by an instruction are undefined.

Programming Note

Application binary interfaces extended to support VSX require special care of vector data written to VSRs 0-31 (i.e., VSRs corresponding to FPRs). Legacy scalar function calls employ doubleword-based loads and stores to preserve the contents of any nonvolatile registers. This has the adverse effect of not preserving the contents of doubleword 1 of these VSRs.

7.1.1.2 Compatibility with Category Vector Operations

The instruction set defined in Chapter 5. Vector Facility [Category: Vector], retains its definition with one primary difference. The VRs are mapped to VSRs 32-63.
7.2 VSX Registers

7.2.1 Vector-Scalar Registers

Sixty-four 128-bit VSRs are provided. See Figure 109. All VSX floating-point computations and other data manipulation are performed on data residing in Vector-Scalar Registers, and results are placed into a VSR.

Depending on the instruction, the contents of a VSR are interpreted as a sequence of equal-length elements (words or doublewords) or as a quadword. Each of the elements is aligned at its natural boundary within the VSR, as shown in Figure 109. Many instructions perform a given operation in parallel on all elements in a VSR. Depending on the instruction, a word element can be interpreted as a signed integer word (SW), an unsigned integer word (UW), a logical mask value (MW), or a single-precision floating-point value (SP); a doubleword element can be interpreted as a doubleword signed integer (SD), a doubleword unsigned integer (UD), a doubleword mask (DM), or a double-precision floating-point value (DP). In the instructions descriptions, phrases like *signed integer word element* are used as shorthand for *word element, interpreted as a signed integer*.

Load and Store instructions are provided that transfer a byte, halfword, word, doubleword, or quadword between storage and a VSR.

*Figure 110. Vector-Scalar Register Elements*

7.2.1.1 Floating-Point Registers

Chapter 4. Floating-Point Facility [Category: Floating-Point] provides 32 64-bit FPRs. Chapter 6. Decimal Floating-Point [Category: Decimal Floating-Point] also employs FPRs in decimal floating-point (DFP) operations. When VSX is implemented, the 32 FPRs are mapped to doubleword 0 of VSRs 0-31. For example, FPR[0] is located in doubleword element 0 of VSR[0], FPR[1] is located in doubleword element 0 of VSR[1], and so forth.

All instructions that operate on an FPR are redefined to operate on doubleword element 0 of the corresponding VSR. The contents of doubleword element 1 of the VSR corresponding to a source FPR or FPR pair for these instructions are ignored and the contents of doubleword element 1 of the VSR corresponding to the target FPR or FPR pair for these instructions are undefined.

7.2.1.2 Vector Registers

Chapter 5. Vector Facility [Category: Vector] provides 32 128-bit VRs. When VSX is implemented, the 32 VRs are mapped to VSRs 32-63. For example, VR[0] is located in VSR[32], VR[1] is located in VSR[33], and so forth. All instructions that operate on a VR are redefined to operate on the corresponding VSR.

Figure 112. Vector Registers as part of VSRs
### 7.2.2 Floating-Point Status and Control Register

The Floating-Point Status and Control Register (FPSCR) controls the handling of floating-point exceptions and records status resulting from the floating-point operations. Bits 0:19 and 32:55 are status bits. Bits 56:63 are control bits.

The exception status bits in the FPSCR (bits 35:44, 53:55) are sticky; that is, once set to 1 they remain set to 1 until they are set to 0 by an `mcrfs`, `mtfsfi`, `mtfsf`, or `mtfsb0` instruction. The exception summary bits in the FPSCR (FX, FEX, and VX, which are bits 32:34) are not considered to be "exception status bits", and only FX is sticky.

#### Programming Note

Access to `Move To FPSCR` and `Move From FPSCR` instructions requires FP=1.

FEX and VX are simply the ORs of other FPSCR bits. Therefore these two bits are not listed among the FPSCR bits affected by the various instructions.

The bit definitions for the FPSCR are as follows.

<table>
<thead>
<tr>
<th>Bits</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0:28</td>
<td>Decimal Floating-Point Rounding Control (DRN)</td>
</tr>
<tr>
<td>32</td>
<td>Floating-Point Exception Summary (FX)</td>
</tr>
<tr>
<td>33</td>
<td>Floating-Point Enabled Exception Summary (FEX)</td>
</tr>
</tbody>
</table>

#### Programming Note

FX is defined not to be altered implicitly by `mtfsfi` and `mtfsf` because permitting these instructions to alter FX implicitly can cause a paradox. An example is an `mtfsfi` or `mtfsf` instruction that supplies 0 for FX and 1 for OX, and is executed when OX=0. See also the Programming Notes with the definition of these two instructions.

34 | Floating-Point Invalid Operation Exception Summary (VX) |
---|---|
| This bit is the OR of all the Invalid Operation exception bits. `mcrfs`, `mtfsfi`, `mtfsf`, and `mtfsb0` cannot alter VX explicitly. |

35 | Floating-Point Overflow Exception (OX) |
---|---|
| This bit is set to 1 when a VSX Scalar Floating-Point Arithmetic, VSX Vector Floating-Point Arithmetic, VSX Scalar DP-SP Conversion class instruction causes an Overflow exception. See Section 7.4.3, “Floating-Point Overflow Exception” on page 351. |
| This bit can be set to 0 or 1 by a `Move To FPSCR` class instruction. |

36 | Floating-Point Underflow Exception (UX) |
---|---|
| This bit is set to 1 when a VSX Scalar Floating-Point Arithmetic, VSX Vector Floating-Point Arithmetic, VSX Scalar DP-SP Conversion class instruction causes an Underflow exception. See Section 7.4.4, “Floating-Point Underflow Exception” on page 353. |
| This bit can be set to 0 or 1 by a `Move To FPSCR` class instruction. |

37 | Floating-Point Zero Divide Exception (ZX) |
---|---|
| This bit is set to 1 when a VSX Scalar Floating-Point Arithmetic or VSX Vector Floating-Point Arithmetic class instruction causes a Zero Divide exception. See Section 7.4.2, “Floating-Point Zero Divide Exception” on page 349. |
| This bit can be set to 0 or 1 by a `Move To FPSCR` class instruction. |

38 | Floating-Point Inexact Exception (XX) |
---|---|
| This bit is set to 1 when a VSX Scalar Floating-Point Arithmetic, VSX Vector Floating-Point Arithmetic, VSX Scalar Integer Conversion, VSX Vector Integer Conversion, VSX Scalar Round to Floating-Point Integer, or VSX Vector Round to Floating-Point Integer class instruction causes an Inexact exception. See Section 7.4.5, “Floating-Point Inexact Exception” on page 356. |
| This bit can be set to 0 or 1 by a `Move To FPSCR` class instruction. |

**Bits 39**: This bit is set to 1 when a VSX Scalar Floating-Point and VSX Vector Floating-Point class instruction causes an SNaN type Invalid Operation exception. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 343.

This bit can be set to 0 or 1 by a Move To FPSCR class instruction.

**Bits 40**: This bit is set to 1 when a VSX Scalar Floating-Point Arithmetic and VSX Vector Floating-Point Arithmetic class instruction causes an Infinity – Infinity type Invalid Operation exception. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 343.

This bit can be set to 0 or 1 by a Move To FPSCR class instruction.

**Bits 41**: This bit is set to 1 when a VSX Scalar Floating-Point Arithmetic and VSX Vector Floating-Point Arithmetic class instruction causes an Infinity ÷ Infinity type Invalid Operation exception. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 343.

This bit can be set to 0 or 1 by a Move To FPSCR class instruction.

**Bits 42**: This bit is set to 1 when a VSX Scalar Floating-Point Arithmetic and VSX Vector Floating-Point Arithmetic class instruction causes a Zero ÷ Zero type Invalid Operation exception. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 343.

This bit can be set to 0 or 1 by a Move To FPSCR class instruction.

**Bits 43**: This bit is set to 1 when a VSX Scalar Floating-Point Arithmetic and VSX Vector Floating-Point Arithmetic class instruction causes an Infinity × Zero type Invalid Operation exception. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 343.

This bit can be set to 0 or 1 by a Move To FPSCR class instruction.

**Bits 44**: This bit is set to 1 when a VSX Scalar Compare Double-Precision, VSX Vector Compare Double-Precision, or VSX Vector Compare Single-Precision class instruction causes an Invalid Compare type Invalid Operation exception. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 343.

This bit can be set to 0 or 1 by a Move To FPSCR class instruction.

**Bits 45**: This bit is set to 0 or 1 by VSX Scalar Floating-Point Arithmetic, VSX Scalar Integer Conversion, and VSX Scalar Round to Floating-Point Integer class instructions to indicate whether or not the fraction was incremented during rounding. See Section 7.3.2.6, “Rounding” on page 335. This bit is not sticky.

**Bits 46**: This bit is set to 0 or 1 by VSX Scalar Floating-Point Arithmetic, VSX Scalar Integer Conversion, and VSX Scalar Round to Floating-Point Integer class instructions to indicate whether or not the rounded result is inexact or the instruction caused a disabled Overflow exception. See Section 7.3.2.6 on page 335. This bit is not sticky.

See the definition of XX, above, regarding the relationship between FI and XX.
Bits Definition

47:51 Floating-Point Result Flags (FPRF) VSX Scalar Floating-Point Arithmetic, VSX Scalar DP-SP Conversion, VSX Scalar Convert Integer to Double-Precision, and VSX Scalar Round to Double-Precision Integer class instructions set this field based on the result placed into the target register and on the target precision, except that if any portion of the result is undefined then the value placed into FPRF is undefined.

For VSX Scalar Convert Double-Precision to Integer class instructions, the value placed into FPRF is undefined.

Additional details are as follows.

47 Floating-Point Result Class Descriptor (C) VSX Scalar Floating-Point Arithmetic, VSX Scalar DP-SP Conversion, VSX Scalar Convert Integer to Double-Precision, and VSX Scalar Round to Double-Precision Integer class instructions set this bit with the FPCC bits, to indicate the class of the result as shown in Table 2, “Floating-Point Result Flags,” on page 327.

48:51 Floating-Point Condition Code (FPCC) VSX Scalar Compare Double-Precision instruction sets one of the FPCC bits to 1 and the other three FPCC bits to 0 based on the relative values of the operands being compared.

VSX Scalar Floating-Point Arithmetic, VSX Scalar DP-SP Conversion, VSX Scalar Convert Integer to Double-Precision, and VSX Scalar Round to Double-Precision Integer class instructions set the FPCC bits with the C bit, to indicate the class of the result as shown in Table 2, “Floating-Point Result Flags,” on page 327. Note that in this case the high-order three bits of the FPCC retain their relational significance indicating that the value is less than, greater than, or equal to zero.

48 Floating-Point Less Than or Negative (FL)

49 Floating-Point Greater Than or Positive (FG)

50 Floating-Point Equal or Zero (FE)

51 Floating-Point Unordered or NaN (FU)

Bits Definition

52 Reserved

53 Floating-Point Invalid Operation Exception (Software-Defined Condition) (VXSOFT) This bit can be altered only by mcrfs, mtfsfi, mtfsf, mtfsb0, or mtfsb1. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 343.

VXSOFT can be used by software to indicate the occurrence of an arbitrary, software-defined, condition that is to be treated as an Invalid Operation exception. For example, the bit could be set by a program that computes a base 10 logarithm if the supplied input is negative.

Floating-Point Invalid Operation Exception (Invalid Square Root) (VXSQRT) This bit is set to 1 when a VSX Scalar Floating-Point Arithmetic or VSX Vector Floating-Point Arithmetic class instruction causes a Invalid Square Root type Invalid Operation exception. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 343.

This bit can be set to 0 or 1 by a Move To FPSCR class instruction.

Floating-Point Invalid Operation Exception (Invalid Integer Convert) (VXCVI) This bit is set to 1 when a VSX Scalar Convert Double-Precision to Integer, VSX Vector Convert Double-Precision to Integer, or VSX Vector Convert Single-Precision to Integer class instruction causes a Invalid Integer Convert type Invalid Operation exception. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 343.

This bit can be set to 0 or 1 by a Move To FPSCR class instruction.

Floating-Point Invalid Operation Exception Enable (VE) This bit is used by VSX Scalar Floating-Point and VSX Vector Floating-Point class instructions to enable trapping on Invalid Operation exceptions. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 343.

Programming Note

When the processor is in floating-point non-IEEE mode, the results of floating-point operations is permitted to be approximate, and performance for these operations might be better, more predictable, or less data-dependent than when the processor is not in non-IEEE mode. For example, in non-IEEE mode an implementation is permitted to return 0 instead of a denormalized number and return a large number instead of an infinity.

7.3 VSX Operations

7.3.1 VSX Floating-Point Arithmetic Overview

This section describes the floating-point arithmetic and exception model supported by category Vector-Scalar Extension. Except for extensions to support 32-bit single-precision floating-point vector operations, the models are identical to that described in Chapter 4. Floating-Point Facility [Category: Floating-Point].

The processor (augmented by appropriate software support, where required) implements a floating-point system compliant with the ANSI/IEEE Standard 754-1985, IEEE Standard for Binary Floating-Point Arithmetic (hereafter referred to as the IEEE standard). That standard defines certain required "operations" (addition, subtraction, and so on). Herein, the term, floating-point operation, is used to refer to one of these required operations and to additional operations defined (e.g., those performed by Multiply-Add or Reciprocal Estimate instructions). A Non-IEEE mode is also provided. This mode, which is permitted to produce results not in strict compliance with the IEEE standard, allows shorter latency.

Instructions are provided to perform arithmetic, rounding, conversion, comparison, and other operations in VSRs; to move floating-point data between storage and these registers.

These instructions are divided into two categories.

- computational instructions
  
The computational instructions are those that perform addition, subtraction, multiplication, division, extracting the square root, rounding, conversion, comparison, and combinations of these operations. These instructions provide the floating-point operations. There are two forms of computational instructions, scalar, which perform a single floating-point operation, and vector, which perform either two double-precision floating-point operations or four single-precision operations. Computational instructions place status information into the Floating-Point Status and Control Register. They are the instructions described in Sections 7.6.1.3 through 7.6.1.72.

- noncomputational instructions
  
The noncomputational instructions are those that perform loads and stores, move the contents of a VSR to another floating-point register possibly altering the sign, and select the value from one of two VSRs based on the value in a third VSR. The operations performed by these instructions are not considered floating-point operations. These instructions do not alter the Floating-Point Status and Control Register. They are the instructions listed in Sections 7.6.1.1, 7.6.1.2.1, and 7.6.1.8 through 7.6.1.9.

A floating-point number consists of a signed exponent and a signed significand. The quantity expressed by this number is the product of the significand and the number $2^{\text{exponent}}$. Encodings are provided in the data format to represent finite numeric values, ±Infinity, and values that are “Not a Number” (NaN). Operations involving infinities produce results obeying traditional mathematical conventions. NaNs have no mathematical interpretation. Their encoding permits a variable diagnostic information field. NaNs might be used to indicate such things as uninitialized variables and can be produced by certain invalid operations.

There is one class of exceptional events that occur during instruction execution that is unique to categories Vector-Scalar Extension and Floating-Point: the Floating-Point Exception. Floating-point exceptions are signaled with bits set in the FPSCR. They can cause the system floating-point enabled exception error handler to be invoked, precisely or imprecisely, if the proper control bits are set.

Floating-Point Exceptions

The following floating-point exceptions are detected by the processor:

- Invalid Operation exception (VX)
  
  - SNaN (VXSNAN)
  - Infinity–Infinity (VXSI)
  - Infinity±Infinity (VXIDI)
  - Zero±Zero (VXZDZ)
  - Infinity×Zero (VXIMZ)
  - Invalid Compare (VXVC)
  - Software-Defined Condition (VXSOFT)
  - Invalid Square Root (VXSQRT)
  - Invalid Integer Convert (VXCVI)
  
- Zero Divide exception (ZX)

- Overflow exception (OX)

- Underflow exception (UX)

- Inexact exception (XX)

Each floating-point exception, and each category of Invalid Operation exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. See Section 7.2.2, “Floating-Point Status and Control Register” on page 323 for a description of these exception and enable bits, and Section 7.3.3, “VSX Floating-Point Execution Models” on page 337 for a detailed discussion of floating-point exceptions, including the effects of the enable bits.
7.3.2 VSX Floating-Point Data

7.3.2.1 Data Format

This architecture defines the representation of a floating-point value in two different binary fixed-length formats, 32-bit single-precision format and 64-bit double-precision format. The single-precision format is used for SP data in storage and registers. The double-precision format is used for DP data in storage and registers.

The lengths of the exponent and the fraction fields differ between these two formats. The structure of the single-precision and double-precision formats is shown below.

Values in floating-point format are composed of three fields:

- **S**: sign bit
- **EXP**: exponent + bias
- **FRACTION**: fraction

Representation of numeric values in the floating-point formats consists of a sign bit (S), a biased exponent (EXP), and the fraction portion (FRACTION) of the significand. The significand consists of a leading implied bit concatenated on the right with the FRACTION. This leading implied bit is 1 for normalized numbers and 0 for denormalized numbers and is located in the unit bit position (that is, the first bit to the left of the binary point). Values representable within the two floating-point formats can be specified by the parameters listed in Table 3.

---

</tr>
</tbody>
</table>

\(\approx\) Value is approximate.

- Dmin: Smallest (in magnitude) representable denormalized number.
- Nmax: Largest (in magnitude) representable number.
- Nmin: Smallest (in magnitude) representable normalized number.
7.3.2.2 Value Representation

This architecture defines numeric and nonnumeric values representable within each of the two supported formats. The numeric values are approximations to the real numbers and include the normalized numbers, denormalized numbers, and zero values. The nonnumeric values representable are the infinities and the Not a Numbers (NaNs). The infinities are adjoined to the real numbers, but are not numbers themselves, and the standard rules of arithmetic do not hold when they are used in an operation. They are related to the real numbers by order alone. It is possible however to define restricted operations among numbers and infinities as defined below. The relative location on the real number line for each of the defined entities is shown in Figure 115.

Figure 115. Approximation to real numbers

The NaNs are not related to the numeric values or infinities by order or value but are encodings used to convey diagnostic information such as the representation of uninitialized variables.

The following is a description of the different floating-point values defined in the architecture:

Binary floating-point numbers
Machine representable values used as approximations to real numbers. Three categories of numbers are supported: normalized numbers, denormalized numbers, and zero values.

Normalized numbers (±NOR)
These are values that have a biased exponent value in the range:

1 to 254 in single-precision format
1 to 2046 in double-precision format

They are values in which the implied unit bit is 1. Normalized numbers are interpreted as follows:

\[ \text{NOR} = (-1)^s \times 2^E \times (1.\text{fraction}) \]

where \( s \) is the sign, \( E \) is the unbiased exponent, and \( 1.\text{fraction} \) is the significand, which is composed of a leading unit bit (implied bit) and a fraction part.

Zero values (±0)
These are values that have a biased exponent value of zero and a fraction value of zero. Zeros can have a positive or negative sign. The sign of zero is ignored by comparison operations (that is, comparison regards +0 as equal to -0).

Denormalized numbers (±DEN)
These are values that have a biased exponent value of zero and a nonzero fraction value. They are nonzero numbers smaller in magnitude than the representable normalized numbers. They are values in which the implied unit bit is 0. Denormalized numbers are interpreted as follows:

\[ \text{DEN} = (-1)^s \times 2^{\text{Emin}} \times (0.\text{fraction}) \]

where \( \text{Emin} \) is the minimum representable exponent value (−126 for single-precision, −1022 for double-precision).

Infinities (±INF)
These are values that have the maximum biased exponent value:

255 in single-precision format
2047 in double-precision format

and a zero fraction value. They are used to approximate values greater in magnitude than the maximum normalized value.

Infinity arithmetic is defined as the limiting case of real arithmetic, with restricted operations defined among numbers and infinities. Infinities and the real numbers can be related by ordering in the affine sense:

\[-\text{Infinity} < \text{every finite number} < +\text{Infinity}\]

Arithmetic on infinities is always exact and does not signal any exception, except when an exception occurs due to the invalid operations as described in Section 7.4.1, "Floating-Point Invalid Operation Exception" on page 343.

For comparison operations, +Infinity compares equal to +Infinity and -Infinity compares equal to -Infinity.

Not a Numbers (NaNs)
These are values that have the maximum biased exponent value and a nonzero fraction value. The sign bit is ignored (that is, NaNs are neither positive nor negative). If the high-order bit of the fraction field is 0, the NaN is a Signaling NaN; otherwise it is a Quiet NaN.

Signaling NaNs are used to signal exceptions when they appear as operands of computational instructions.
Quiet NaNs are used to represent the results of certain invalid operations, such as invalid arithmetic operations on infinities or on NaNs, when Invalid Operation exception is disabled (VE=0). Quiet NaNs propagate through all floating-point operations except ordered comparison and conversion to integer. Quiet NaNs do not signal exceptions, except for ordered comparison and conversion to integer operations. Specific encodings in QNaNs can thus be preserved through a sequence of floating-point operations, and used to convey diagnostic information to help identify results from invalid operations.

Assume the following generic arithmetic templates.

\[
\begin{align*}
&f(src1, src3, src2) \\
&\text{ex: result} = (src1 \times src3) - src2 \\
&f(src1, src2) \\
&\text{ex: result} = src1 \times src2 \\
&\text{ex: result} = src1 + src2 \\
&f(src1) \\
&\text{ex: result} = f(src1)
\end{align*}
\]

When a QNaN is the result of a floating-point operation because one of the operands is a NaN or because a QNaN was generated due to a trap-disabled Invalid Operation exception, the following rule is applied to determine the NaN with the high-order fraction bit set to 1 that is to be stored as the result.

\[
\begin{align*}
&\text{if src1 is a NaN} \\
&\quad \text{then result} = \text{Quiet}(src1) \\
&\text{else if src2 is a NaN (if there is a src2)} \\
&\quad \text{then result} = \text{Quiet}(src2) \\
&\text{else if src3 is a NaN (if there is a src3)} \\
&\quad \text{then result} = \text{Quiet}(src3) \\
&\text{else if disabled invalid operation exception} \\
&\quad \text{then result} = \text{generated QNaN}
\end{align*}
\]

where Quiet(x) means x if x is a QNaN and x converted to a QNaN if x is an SNaN. Any instruction that generates a QNaN as the result of a disabled Invalid Operation exception generates the value 0x7FF8_0000_0000_0000 for double-precision and 0x7FC0_0000 for single-precision.

Note that the M-form multiply-add-type instructions use the B source operand to specify src3 and the T target operand to specify src2, whereas A-form multiply-add-type instructions use the B source operand to specify src2 and the T target operand to specify src3.

A double-precision NaN is considered to be representable in single-precision format if and only if the low-order 29 bits of the double-precision NaN’s fraction are zero.

### 7.3.2.3 Sign of Result

The following rules govern the sign of the result of an arithmetic, rounding, or conversion operation, when the operation does not yield an exception. They apply even when the operands or results are zeros or infinities.

- The sign of the result of an add operation is the sign of the operand having the larger absolute value. If both operands have the same signs, the sign of the result of an add operation is the same as the sign of the operands. The sign of the result of the subtract operation \(x - y\) is the same as the sign of the result of the add operation \(x + (-y)\).

When the sum of two operands with opposite sign, or the difference of two operands with the same signs, is exactly zero, the sign of the result is positive in all rounding modes except Round toward –Infinity, in which mode the sign is negative.

- The sign of the result of a multiply or divide operation is the Exclusive OR of the signs of the operands.

- The sign of the result of a Square Root or Reciprocal Square Root Estimate operation is always positive, except that the square root of \(-0\) is \(-0\) and the reciprocal square root of \(-0\) is \(-\infty\).

- The sign of the result of a Convert From Integer or Round to Floating-Point Integer operation is the sign of the operand being converted.

For the Multiply-Add instructions, the rules given above are applied first to the multiply operation and then to the add or subtract operation (one of the inputs to the add or subtract operation is the result of the multiply operation).

### 7.3.2.4 Normalization and Denormalization

The intermediate result of an arithmetic instruction can require normalization and/or denormalization as described below. Normalization and denormalization do not affect the sign of the result.

When an arithmetic or rounding instruction produces an intermediate result which carries out of the
significand, or in which the significand is nonzero but has a leading zero bit, it is not a normalized number and must be normalized before it is stored. For the carry-out case, the significand is shifted right one bit, with a one shifted into the leading significand bit, and the exponent is incremented by one. For the leading-zero case, the significand is shifted left while decrementing its exponent by one for each bit shifted, until the leading significand bit becomes one. The Guard bit and the Round bit (see Section 7.3.3.1, “VSX Execution Model for IEEE Operations” on page 337) participate in the shift with zeros shifted into the Round bit. The exponent is regarded as if its range were unlimited.

After normalization, or if normalization was not required, the intermediate result can have a nonzero significand and an exponent value that is less than the minimum value that can be represented in the format specified for the result. In this case, the intermediate result is said to be “Tiny” and the stored result is determined by the rules described in Section 7.4.4, “Floating-Point Underflow Exception” on page 353. These rules can require denormalization.

A number is denormalized by shifting its significand right while incrementing its exponent by 1 for each bit shifted, until the exponent is equal to the format’s minimum value. If any significant bits are lost in this shifting process, “Loss of Accuracy” has occurred (See Section 7.4.4, “Floating-Point Underflow Exception” on page 353) and Underflow exception is signaled.

Engineering Note
When denormalized numbers are operands of multiply, divide, and square root operations, some implementations might prenormalize the operands internally before performing the operations.

7.3.2.5 Data Handling and Precision

Scalar double-precision floating-point data is represented in double-precision format in VSRs and storage.

Vector double-precision floating-point data is represented in double-precision format in VSRs and storage.

Scalar single-precision floating-point data is represented in double-precision format in VSRs and single-precision format in storage.

Vector single-precision floating-point data is represented in single-precision format in VSRs and storage.

Double-precision operands may be used as input for double-precision scalar arithmetic operations.

Double-precision operands may be used as input for single-precision scalar arithmetic operations when trapping on overflow and underflow exceptions is disabled.

Single-precision operands may be used as input for double-precision and single-precision scalar arithmetic operations.

Double-precision operands may be used as input for double-precision vector arithmetic operations.

Single-precision operands may be used as input for single-precision vector arithmetic operations.

Instructions are also provided for manipulations which do not require double-precision or single-precision. In addition, instructions are provided to access an integer representation in GPRs.

Single-Precision Operands

For single-precision scalar data, a conversion from single-precision format to double-precision format is performed when loading from storage into a VSR and a conversion from double-precision format to single-precision format is performed when storing from a VSR to storage. No floating-point exceptions are caused by these instructions.

Instructions are provided to convert between single-precision and double-precision formats for scalar and vector data in VSRs.

An instruction is provided to explicitly convert a double format operand in a VSR to single-precision. Scalar single-precision floating-point is enabled with six types of instruction.

1. Load Scalar Single-Precision
   This form of instruction accesses a floating-point operand in single-precision format in storage, converts it to double-precision format, and loads it into a VSR. No floating-point exceptions are caused by these instructions.

2. Scalar Round to Single-Precision
   \texttt{xrsps} rounds a double-precision operand to single-precision, checking the exponent for single-precision range and handling any exceptions according to respective enable bits, and places that operand into a VSR in double-precision format. For results produced by single-precision arithmetic instructions, single-precision loads, and other instances of
**xsresp, xsrsp** does not alter the value. Values greater in magnitude than $2^{319}$ when Overflow is enabled (OE=1) produce undefined results because the value cannot be scaled back into the normalized range. Values smaller in magnitude than $2^{-318}$ when Underflow is enabled (UE=1) produce undefined results because the value cannot be scaled back into the normalized range.

3. **Scalar Convert Single-Precision to Double-Precision**

*xscvdpdp* accesses a floating-point operand in single-precision format from word element 0 of the source VSR, converts it to double-precision format, and places it into doubleword element 0 of the target VSR.

4. **Scalar Convert Double-Precision to Single-Precision**

*xscvdpsp* rounds the double-precision floating-point value in doubleword element 0 of the source VSR to single-precision, and places the result into word element 0 of the target VSR in single-precision format. This function would be used to port scalar floating-point data to a format compatible for single-precision vector operations. Values greater in magnitude than $2^{319}$ when Overflow is enabled (OE=1) produce undefined results because the value cannot be scaled back into the normalized range. Values smaller in magnitude than $2^{-318}$ when Underflow is enabled (UE=1) produce undefined results because the value cannot be scaled back into the normalized range.

5. **VSX Scalar Single-Precision Arithmetic**

This form of instruction takes operands from the VSRs in double format, performs the operation as if it produced an intermediate result having infinite precision and unbounded exponent range, and then coerces this intermediate result to fit in single-precision format. Status bits, in the FPSCR and optionally in the Condition Register, are set to reflect the single-precision result. The result is then placed into the target VSR in double-precision format. The result lies in the range supported by the single format.

If any input value is not representable in single-precision format and either OE=1 or UE=1, the result placed into the target VSR and the setting of status bits in the FPSCR are undefined.

For *xsresp* or *xsrqrtresp*, if the input value is finite and has an unbiased exponent greater than $+127$, the input value is interpreted as an Infinity.

6. **Store VSX Scalar Single-Precision**

*stxspx* converts a single-precision value that is in double-precision format to single-precision format and stores that operand into storage. No floating-point exceptions are caused by *stxspx*. (The value being stored is effectively assumed to be the result of an instruction of one of the preceding five types.)

When the result of a *Load VSX Scalar Single-Precision* (*lxsspx*), a *VSX Scalar Round to Single-Precision* (*xsrsp*), or a *VSX Scalar Single-Precision Arithmetic* instruction is stored in a VSR, the low-order 29 bits of FRACTION are zero.

---

**Programming Note**

VSX Scalar Round to Single-Precision (*xsrsp*) is provided to allow value conversion from double-precision to single-precision with appropriate exception checking and rounding. *xsrsp* should be used to convert double-precision floating-point values to single-precision values prior to storing them into single format storage elements or using them as operands for single-precision arithmetic instructions. Values produced by single-precision load and arithmetic instructions are already single-precision values and can be stored directly into single format storage elements, or used directly as operands for single-precision arithmetic instructions, without preceding the store, or the arithmetic instruction, by an *xsrsp*.

---

1. VSX Scalar Single-Precision Arithmetic instructions:
   * xsaddsp, xsdivsp, xsmulsp, xsresp, xssubsp, xsmdasp, xsmaddsp, xsmsubasp, xsmsubbsp, xsnmaddsp, xsnmaddssp, xsnmmsubasp, xsnmmsubbsp
Integer-Valued Operands

Instructions are provided to round floating-point operands to integer values in floating-point format. To facilitate exchange of data between the floating-point and integer processing, instructions are provided to convert between floating-point double and single-precision format and integer word and doubleword format in a VSR. Computation on integer-valued operands can be performed using arithmetic instructions of the required precision. (The results might not be integer values.) The three groups of instructions provided specifically to support integer-valued operands are described below.

1. Rounding to a floating-point integer

   a. VSX Scalar Round to Double-Precision Integer
      - VSX Scalar Round to Double-Precision Integer instructions round a double-precision operand to an integer value in double-precision format.
      - VSX Vector Round to Double-Precision Integer instructions round each double-precision vector operand element to an integer value in double-precision format.

   b. VSX Vector Round to Single-Precision Integer
      - VSX Vector Round to Single-Precision Integer instructions round each single-precision vector operand element to an integer value in single-precision format.

   c. VSX Round to Floating-Point Integer
      - VSX Round to Floating-Point Integer instructions can cause Invalid Operation (VXSNAN) exceptions.

   d. VSX Scalar Double-Precision to Integer Format Conversion
      - VSX Scalar Double-Precision to Integer Format Conversion instructions convert a double-precision operand to 32-bit or 64-bit signed or unsigned integer format.

   e. VSX Vector Double-Precision to Integer Format Conversion
      - VSX Vector Double-Precision to Integer Format Conversion instructions convert either double-precision or single-precision vector operand elements to 32-bit or 64-bit signed or unsigned integer format.

   f. VSX Vector Single-Precision to Integer Word Format Conversion
      - VSX Vector Single-Precision to Integer Word Format Conversion instructions convert the single-precision value in each odd-numbered word element of the source vector operand to a 64-bit signed or unsigned integer format.

   g. VSX Vector Single-Precision to Integer Format Conversion
      - VSX Vector Single-Precision to Integer Format Conversion instructions convert the single-precision value in each word element of the source vector operand to either a 32-bit signed or unsigned integer format.

1. VSX Scalar Round to Double-Precision Integer instructions:
   - xsrds, xsrdps, xsrdpm, xsrdpi, xsrdp
2. VSX Vector Round to Double-Precision Integer instructions:
   - xvrdps, xvrdpp, xvrdpm, xvrdpi, xvrdp
3. VSX Vector Round to Single-Precision Integer instructions:
   - xvrsii, xvrsipi, xvrsipim, xvrsipi, xvrszip
4. VSX Round to Floating-Point Integer instructions:
   - xsrdpi, xsrds, xsrdpm, xsrdpi, xsrds, xsrdpi, xvrdps, xvrdpp, xvrdpm, xvrdpi, xvrdp
5. VSX Scalar Double-Precision to Integer Format Conversion instructions:
   - xsuvdpsxds, xsvdpxsws, xsvdpxuds, xsuvdpxws
6. VSX Vector Double-Precision to Integer Format Conversion instructions:
   - xecvpsxws, xecvdpxws, xevdpxuds, xecvpsxws, xevdpxws
7. VSX Vector Single-Precision to Integer Doubleword Format Conversion instructions:
   - xevpspxws, xevpsxws
8. VSX Vector Single-Precision to Integer Word Format Conversion instructions:
   - xevpspxws, xevpsxws
Rounding is performed using Round Towards Zero rounding mode. These instructions can cause Invalid Operation (VXSNAN, VXCVI) and Inexact exceptions.

3. Converting integer format to floating-point format

VSX Scalar Integer Doubleword to Double-Precision Format Conversion\[^{[1]}\] instructions convert a 64-bit signed or unsigned integer to a double-precision floating-point value and returns the result in double-precision format.

VSX Scalar Integer Doubleword to Single-Precision Format Conversion\[^{[2]}\] instructions converts a 64-bit signed or unsigned integer to a single-precision floating-point value and returns the result in double-precision format.

VSX Vector Integer Doubleword to Double-Precision Format Conversion\[^{[3]}\] instructions converts the 64-bit signed or unsigned integer in each doubleword element in the source vector operand to double-precision floating-point format.

VSX Vector Integer Doubleword to Single-Precision Format Conversion\[^{[4]}\] instructions convert the 64-bit signed or unsigned integer in each doubleword element in the source vector operand to single-precision floating-point format.

VSX Vector Integer Word to Double-Precision Format Conversion\[^{[5]}\] instructions converts the 32-bit signed or unsigned integer in each odd-numbered word element in the source vector operand to double-precision floating-point format.

VSX Vector Integer Word to Single-Precision Format Conversion\[^{[6]}\] instructions convert the 32-bit signed or unsigned integer in each word element in the source vector operand to single-precision floating-point format.

Rounding is performed using the rounding mode specified in RN. Because of the limitations of the source format, only an Inexact exception can be generated.

7.3.2.6 Rounding

The material in this section applies to operations that have numeric operands (that is, operands that are not infinities or NaNs). Rounding the intermediate result of such an operation can cause an Overflow exception, an Underflow exception, or an Inexact exception. The remainder of this section assumes that the operation causes no exceptions and that the result is numeric. See Section 7.3.2.2, “Value Representation” and Section 7.4, “VSX Floating-Point Exceptions” for the cases not covered here.

The floating-point arithmetic, and rounding and conversion instructions round their intermediate results. With the exception of the estimate instructions, these instructions produce an intermediate result that can be regarded as having unbounded precision and exponent range. All but two groups of these instructions normalize or denormalize the intermediate result prior to rounding and then place the final result into the target element of the target VSR in either double or single-precision format.

The scalar round to double-precision integer, vector round to double-precision integer, and convert double-precision to integer instructions with biased exponents ranging from 1022 through 1074 are prepared for rounding by repetitively shifting the significand right one position and incrementing the biased exponent until it reaches a value of 1075. (Intermediate results with biased exponents 1075 or larger are already integers, and with biased exponents 1021 or less round to zero.) After rounding, the final result for round to double-precision integer instructions is normalized and put in double-precision format, and, for the convert double-precision to integer instructions, is converted to a signed or unsigned integer.

The vector round to single-precision integer and vector convert single-precision to integer instructions with biased exponents ranging from 126 through 178 are prepared for rounding by repetitively shifting the significand right one position and incrementing the biased exponent until it reaches a value of 179. (Intermediate results with biased exponents 179 or larger are already integers, and with biased exponents 125 or less round to zero.) After rounding, the final result for vector round to single-precision integer is normalized and put in double-precision format, and for
vector convert single-precision to integer is converted to a signed or unsigned integer.

FR and FI generally indicate the results of rounding. Each of the scalar instructions which rounds its intermediate result sets these bits. There are no vector instructions that modify FR and FI. If the fraction is incremented during rounding, FR is set to 1, otherwise FR is set to 0. If the result is inexact, FI is set to 1, otherwise FI is set to zero. The scalar round to double-precision integer instructions are exceptions to this rule, setting FR and FI to 0. The scalar double-precision estimate instructions set FR and FI to undefined values. The remaining scalar floating-point instructions do not alter FR and FI.

Four user-selectable rounding modes are provided through the Floating-Point Rounding Control field in the FPSCR. See Section 7.2.2, “Floating-Point Status and Control Register” on page 323. These are encoded as follows.

<table>
<thead>
<tr>
<th>RN</th>

</tr>
<tr>
<td>11</td>
<td>Round towards -Infinity</td>
</tr>
</tbody>
</table>

A fifth rounding mode is provided in the round to floating-point integer instructions (Section 7.6.1.7.2 on page 368), Round to Nearest Away.

Let Z be the intermediate arithmetic result or the operand of a convert operation. If Z can be represented exactly in the target format, the result in all rounding modes is Z as represented in the target format. If Z cannot be represented exactly in the target format, let Z1 and Z2 bound Z as the next larger and next smaller numbers representable in the target format. Then Z1 or Z2 can be used to approximate the result in the target format.

Figure 116 shows the relation of Z, Z1, and Z2 in this case. The following rules specify the rounding in the four modes.

See Section 7.3.3.1, “VSX Execution Model for IEEE Operations” on page 337 for a detailed explanation of rounding.

Figure 116 also summarizes the rounding actions for floating-point intermediate result for all supported rounding modes.

```
Round to Nearest Away
Choose the value that is closer to Z (Z1 or Z2). In case of a tie, choose the one that is furthest away from 0.

Round to Nearest Even
Choose the value that is closer to Z (Z1 or Z2). In case of a tie, choose the one that is even (least significant bit is 0).

Round toward Zero
Choose the smaller in magnitude (Z1 or Z2).

Round toward +Infinity
Choose Z1.

Round toward -Infinity
Choose Z2.
```

Figure 116.Selection of Z1 and Z2
7.3.3 VSX Floating-Point Execution Models

All implementations of this architecture must provide the equivalent of the following execution models to ensure that identical results are obtained.

Special rules are provided in the definition of the computational instructions for the infinities, denormalized numbers and NaNs. The material in the remainder of this section applies to instructions that have numeric operands and a numeric result (that is, operands and result that are not infinities or NaNs), and that cause no exceptions. See Section 7.3.2.2 and Section 7.3.3 for the cases not covered here.

Although the double-precision format specifies an 11-bit exponent, exponent arithmetic makes use of two additional bits to avoid potential transient overflow and underflow conditions. One extra bit is required when denormalized double-precision numbers are prenormalized. The second bit is required to permit the computation of the adjusted exponent value in the following cases when the corresponding exception enable bit is 1:

- Underflow during multiplication using a denormalized operand.
- Overflow during division using a denormalized divisor.
- Underflow during division using denormalized dividend and a large divisor.

The IEEE standard includes 32-bit and 64-bit arithmetic. The standard requires that single-precision arithmetic be provided for single-precision operands.

VSX defines both scalar and vector double-precision floating-point operations to operate only on double-precision operands. VSX also defines vector single-precision floating-point operations to operate only on single-precision operands.

7.3.3.1 VSX Execution Model for IEEE Operations

The following description uses 64-bit arithmetic as an example. 32-bit arithmetic is similar except that the FRACTION is a 23-bit field, and the single-precision Guard, Round, and Sticky bits (described in this section) are logically adjacent to the 23-bit FRACTION field.

IEEE-conforming significand arithmetic is considered to be performed with a floating-point accumulator having the following format, where bits 0:55 comprise the significand of the intermediate result.

```
SCL  FRACTION  G  R  X
0 1 53 54 55
```

Figure 117. IEEE floating-point execution model

The S bit is the sign bit.

The C bit is the carry bit, which captures the carry out of the significand.

The L bit is the leading unit bit of the significand, which receives the implicit bit from the operand.

The FRACTION is a 52-bit field that accepts the fraction of the operand.

The Guard (G), Round (R), and Sticky (X) bits are extensions to the low-order bits of the accumulator. The G and R bits are required for postnormalization of the result. The G, R, and X bits are required during rounding to determine if the intermediate result is equally near the two nearest representable values. The X bit serves as an extension to the G and R bits by representing the logical OR of all bits that appear to the low-order side of the R bit, resulting from either shifting the accumulator right or to other generation of low-order result bits. The G and R bits participate in the left shifts with zeros being shifted into the R bit. Table 4 shows the significance of the G, R, and X bits with respect to the intermediate result (IR), the representable number next lower in magnitude (NL), and the representable number next higher in magnitude (NH).

</table>

Table 5. Location of the Guard, Round, and Sticky bits in the IEEE execution model

The significand of the intermediate result is prepared for rounding by shifting its contents right, if required, until the least significant bit to be retained is in the low-order bit position of the fraction.

Four user-selectable rounding modes are provided through RN as described in Section 7.3.2.6, “Rounding” on page 335. The rules for rounding in each mode are as follows.

– **Round to Nearest Even**
  
  **Guard bit = 0**
  
  The result is truncated.
  
  **Guard bit = 1**
  
  Depends on Round and Sticky bits:
  
  **Case a**
  
  If the Round or Sticky bit is 1 (inclusive), the result is incremented.
  
  **Case b**
  
  If the Round and Sticky bits are 0 (result midway between closest representable values), if the low-order bit of the result is 1, the result is incremented. Otherwise (the low-order bit of the result is 0), the result is truncated. This is the case of a tie rounded to even.

– **Round toward Zero**
  
  Choose the smaller in magnitude of Z₁ or Z₂. If the Guard, Round, or Sticky bit is nonzero, the result is inexact.
  
  The result is truncated.

– **Round toward +Infinity**
  
  If positive, the result is incremented.
  
  If negative, the result is truncated.

– **Round toward −Infinity**
  
  If positive, the result is truncated.
  
  If negative, the result is incremented.

A fifth rounding mode is provided in the VSX Round to Floating-Point Integer instructions (Section 7.6.1.7.2 on page 368) with the rules for rounding as follows.

– **Round to Nearest Away**
  
  **Guard bit = 0**
  
  The result is truncated.
  
  **Guard bit = 1**
  
  The result is incremented.

If any of the Guard, Round, or Sticky bits is nonzero, the result is also inexact.

If rounding results in a carry into C, the significand is shifted right one position and the exponent is incremented by one. This yields an inexact result, and possibly also exponent overflow. Fraction bits are stored to the target VSR.

### 7.3.3.2 VSX Execution Model for Multiply-Add Type Instructions

This architecture provides a special form of instruction that performs up to three operations in one instruction (a multiplication, an addition, and a negation). With this added capability comes the special ability to produce a more exact intermediate result as input to the rounder.

32-bit arithmetic is similar, except that the FRACTION field is smaller.

Multiply-add significand arithmetic is considered to be performed with a floating-point accumulator having the following format, where bits 0:106 comprise the significand of the intermediate result.

![Multiply-add 64-bit execution model](image)

Figure 118. Multiply-add 64-bit execution model

The first part of the operation is a multiplication. The multiplication has two 53-bit significands as inputs, which are assumed to be prenormalized, and produces a result conforming to the above model. If there is a carry out of the significand (into the C bit), the significand is shifted right one position, shifting the L bit (leading unit bit) into the most significant bit of the FRACTION and shifting the C bit (carry out) into the L bit. All 106 bits (L bit, the FRACTION) of the product take part in the add operation. If the exponents of the two inputs to the adder are not equal, the significand of the operand with the smaller exponent is aligned (shifted) to the right by an amount that is added to that exponent to make it equal to the other input’s exponent. Zeros are shifted into the left of the significand as it is aligned and bits shifted out of bit 105 of the significand are ORed into the X’ bit. The add
operation also produces a result conforming to the above model with the $X'$ bit taking part in the add operation.

The result of the addition is then normalized, with all bits of the addition result, except the $X'$ bit, participating in the shift. The normalized result serves as the intermediate result that is input to the rounder.

For rounding, the conceptual Guard, Round, and Sticky bits are defined in terms of accumulator bits. Figure 6 shows the positions of the Guard, Round, and Sticky bits for double-precision and single-precision floating-point numbers in the multiply-add execution model.

<table>
<thead>
<tr>
<th>Format</th>
<th>Guard</th>
<th>Round</th>
<th>Sticky</th>
</tr>
</thead>
<tbody>
<tr>
<td>Double</td>
<td>53</td>
<td>54</td>
<td>OR of 55:105, $X'$</td>
</tr>
<tr>
<td>Single</td>
<td>24</td>
<td>25</td>
<td>OR of 26:105, $X'$</td>
</tr>
</tbody>
</table>

Table 6. Location of the Guard, Round, and Sticky bits in the multiply-add execution model

The rules for rounding the intermediate result are the same as those given in Section 7.3.3.1.

If the instruction is a negative multiply-add or negative multiply-subtract type instruction, the final result is negated.
7.4 VSX Floating-Point Exceptions

This architecture defines the following floating-point exceptions under the IEEE-754 exception model:

- Invalid Operation exception
  - SNaN
  - Infinity ÷ Infinity
  - Infinity ÷ Zero
  - Infinity × Zero
  - Invalid Compare
  - Software-Defined Condition
  - Invalid Square Root
  - Invalid Integer Convert
- Zero Divide exception
- Overflow exception
- Underflow exception
- Inexact exception

These exceptions, other than Invalid Operation exception resulting from a Software-Defined Condition, can occur during execution of computational instructions. An Invalid Operation exception resulting from a Software-Defined Condition occurs when a Move To FPSCR instruction sets VXSOFT to 1.

Each floating-point exception, and each category of Invalid Operation exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. The exception bit indicates the occurrence of the corresponding exception. If an exception occurs, the corresponding enable bit governs the result produced by the instruction and, in conjunction with the FE0 and FE1 bits (see page 341), whether and how the system floating-point enabled exception error handler is invoked. In general, the enabling specified by the enable bit is of invoking the system error handler, not of permitting the exception to occur. The occurrence of an exception depends only on the instruction and its inputs, not on the setting of any control bits. The only deviation from this general rule is that the occurrence of an Underflow exception depends on the setting of the enable bit.

A single instruction, other than mtfsfi or mtfsf, can set more than one exception bit only in the following cases:

- An Inexact exception can be set with an Overflow exception.
- An Inexact exception can be set with an Underflow exception.
- An Invalid Operation exception (SNaN) is set with an Invalid Operation exception (Infinity × 0) for multiply-add class instructions for which the values being multiplied are infinity and zero and the value being added is an SNaN.
- An Invalid Operation exception (SNaN) can be set with an Invalid Operation exception (Invalid Compare) for ordered comparison instructions.
- An Invalid Operation exception (SNaN) can be set with an Invalid Operation exception (Invalid Integer Convert) for convert to integer instructions.

When an exception occurs, the writing of a result to the target register can be suppressed, or a result can be delivered, depending on the exception.

The writing of a result to the target register is suppressed for the certain kinds of exceptions, based on whether the instruction is a vector or a scalar instruction, so that there is no possibility that one of the operands is lost. For other kinds of exceptions and also depending on whether the instruction is a vector or a scalar instruction, a result is generated and written to the destination specified by the instruction causing the exception. The result can be a different value for the enabled and disabled conditions for some of these exceptions. Table 7 lists the types of exceptions and indicates whether a result is written to the target VSR or suppressed.

<table>
<thead>
<tr>

<tr>
<td>Disabled Invalid Operation</td>
<td>written</td>
<td>written</td>
</tr>
</tbody>
</table>

Table 7. Exception Types Result Suppression
The subsequent sections define each of the floating-point exceptions and specify the action that is taken when they are detected.

The IEEE standard specifies the handling of exceptional conditions in terms of traps and trap handlers. In this architecture, an FPSCR exception enable bit of 1 causes generation of the result value specified in the IEEE standard for the trap enabled case; the expectation is that the exception is detected by software, which revises the result. An FPSCR exception enable bit of 0 causes generation of the default result value specified for the trap disabled (or no trap occurs or trap is not implemented) case. The expectation is that the exception is not detected by software, which uses the default result. The result to be delivered in each case for each exception is described in the following sections.

The IEEE default behavior when an exception occurs is to generate a default value and not to notify software. In this architecture, if the IEEE default behavior when an exception occurs is required for all exceptions, all FPSCR exception enable bits must be set to 0, and Ignore Exceptions Mode (see below) should be used. In this case, the system floating-point enabled exception error handler is not invoked, even if floating-point exceptions occur: software can inspect the FPSCR exception bits, if necessary, to determine whether exceptions have occurred.

In this architecture, if software is to be notified that a given kind of exception has occurred, the corresponding FPSCR exception enable bit must be set to 1, and a mode other than Ignore Exceptions Mode must be used. In this case, the system floating-point enabled exception error handler is invoked if an enabled floating-point exception occurs. The system floating-point enabled exception error handler is also invoked if a Move To FPSCR instruction causes an exception bit and the corresponding enable bit both to be 1. The Move To FPSCR instruction is considered to cause the enabled exception.

The FE0 and FE1 bits control whether and how the system floating-point enabled exception error handler is invoked if an enabled floating-point exception occurs. The location of these bits and the requirements for altering them are described in Book III. The system floating-point enabled exception error handler is never invoked because of a disabled floating-point exception. The effects of the four possible settings of these bits are as follows.

### FE0 FE1 Description

<table>
<thead>
<tr>
<th>FE0</th>
<th>FE1</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<td>Imprecise Recoverable Mode</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Precise Mode</td>
</tr>
</tbody>
</table>

Floating-point exceptions do not cause the system floating-point enabled exception error handler to be invoked.

The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. It may not be possible to identify the excepting instruction or the data that caused the exception. Results produced by the excepting instruction might have been used by or might have affected subsequent instructions that are executed before the error handler is invoked.

The system floating-point enabled exception error handler is invoked precisely at the instruction that caused the enabled exception.

The FE0 and FE1 bits must be defined in Book III in a manner such that they can be changed dynamically and can easily be treated as part of a process’ state.

In all cases, the question of whether a floating-point result is stored, and what value is stored, is governed by the FPSCR exception enable bits, as described in subsequent sections, and is not affected by the value of the FE0 and FE1 bits.

In all cases in which the system floating-point enabled exception error handler is invoked, all instructions before the instruction at which the system...
floating-point enabled exception error handler is invoked have been completed, and no instruction after the instruction at which the system floating-point enabled exception error handler is invoked has begun execution. The instruction at which the system floating-point enabled exception error handler is invoked has completed if it is the excepting instruction, and there is only one such instruction. Otherwise, it has not begun execution, or has been partially executed in some cases, as described in Book III.

To obtain the best performance across the widest range of implementations, the programmer should obey the following guidelines.

- If the IEEE default results are acceptable to the application, Ignore Exceptions Mode should be used with all FPSCR exception enable bits set to 0.
- If the IEEE default results are not acceptable to the application, Imprecise Nonrecoverable Mode should be used, or Imprecise Recoverable Mode if recoverability is needed, with FPSCR exception enable bits set to 1 for those exceptions for which the system floating-point enabled exception error handler is to be invoked.
- Ignore Exceptions Mode should not, in general, be used when any FPSCR exception enable bits are set to 1.
- Precise Mode can degrade performance in some implementations, perhaps substantially, and therefore should be used only for debugging and other specialized applications.

In any of the three non-Precise modes, a Floating-Point Status and Control Register instruction can be used to force any exceptions, because of instructions initiated before the Floating-Point Status and Control Register instruction, to be recorded in the FPSCR. (This forcing is superfluous for Precise Mode.)

In both Imprecise modes, a Floating-Point Status and Control Register instruction can be used to force any invocations of the system floating-point enabled exception error handler that result from instructions initiated before the Floating-Point Status and Control Register instruction to occur. This forcing has no effect in Ignore Exceptions Mode, and is superfluous for Precise Mode.

The last sentence of the paragraph preceding this Programming Note can apply only in the Imprecise modes, or if the mode has just been changed from Ignore Exceptions Mode to some other mode. It always applies in the latter case.

It is permissible for the implementation to be precise in any of the three modes that permit interrupts, or to be recoverable in Nonrecoverable Mode.
7.4.1 Floating-Point Invalid Operation Exception

7.4.1.1 Definition

An Invalid Operation exception occurs when an operand is invalid for the specified operation. The invalid operations are:

**SNaN**
Any floating-point operation on a Signaling NaN.

**Infinity–Infinity**
Magnitude subtraction of infinities.

**Infinity×Infinity**
Floating-point division of infinity by infinity.

**Zero÷Zero**
Floating-point division of zero by zero.

**Infinity × Zero**
Floating-point multiplication of infinity by zero.

**Invalid Compare**
Floating-point ordered comparison involving a NaN.

**Invalid Square Root**
Floating-point square root or reciprocal square root of a nonzero negative number.

**Invalid Integer Convert**
Floating-point-to-integer convert involving a number too large in magnitude to be represented in the target format, or involving an infinity or a NaN.

An Invalid Operation exception also occurs when an *mtfsfi*, *mtfsf*, or *mtfsb1* instruction is executed that sets VXSOFT to 1 (Software-Defined Condition).

The action to be taken depends on the setting of the Invalid Operation Exception Enable bit of the FPSCR.

7.4.1.2 Action for VE=1

When Invalid Operation exception is enabled (VE=1) and an Invalid Operation exception occurs, the following actions are taken:

For *VSX Scalar Floating-Point Arithmetic, VSX Scalar DP-SP Conversion, VSX Scalar Convert Floating-Point to Integer, and VSX Scalar Round to Floating-Point Integer* instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN (if SNaN)
   VXISI (if Infinity–Infinity)
   VXIDI (if Infinity×Infinity)
   VXZDZ (if Zero÷Zero)
   VXIMZ (if Infinity×Zero)
   VXSQRT (if Invalid Square Root)
   VXCVI (if Invalid Integer Convert)

2. Update of VSR[XT] is suppressed.

3. FR and FI are set to zero.

4. FPRF is unchanged.

For *VSX Scalar Floating-Point Compare* instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.

   VXSNAN (if SNaN)
   VXVC (if Invalid Compare)

2. FR, FI, and C are unchanged.

3. FPCC is set to reflect unordered.

For *VSX Vector Floating-Point Arithmetic, VSX Vector Floating-Point Compare, VSX Vector DP-SP Conversion, VSX Vector Convert Floating-Point to Integer, and VSX Vector Round to Floating-Point Integer* instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.

   VXSNAN (if SNaN)
   VXISI (if Infinity–Infinity)
   VXIDI (if Infinity×Infinity)
   VXZDZ (if Zero÷Zero)
   VXIMZ (if Infinity×Zero)
   VXVC (if Invalid Compare)
   VXSQRT (if Invalid Square Root)
   VXCVI (if Invalid Integer Convert)

2. Update of VSR[XT] is suppressed for all vector elements.

3. FR and FI are unchanged.

4. FPRF is unchanged.
7.4.1.3 Action for VE=0

When Invalid Operation exception is disabled (VE=0) and an Invalid Operation exception occurs, the following actions are taken:

For the VSX Scalar round and Convert Double-Precision to Single-Precision format (xscvdpsp) instruction:

1. VXSNAN is set to 1.

2. The single-precision representation of a Quiet NaN is placed into word element 0 of VSR[XT]. The contents of word elements 1-3 of VSR[XT] are undefined.

3. FR and FI are set to 0.

4. FPRF is set to indicate the class of the result (Quiet NaN).

For the VSX Vector Single-Precision Arithmetic instructions, VSX Vector Single-Precision Maximum/Minimum instructions, the VSX Vector round and Convert Double-Precision to Single-Precision format (xvcvdpsp) instruction, and the VSX Vector Round to Single-Precision Integer instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.
   - VXSNAN (if SNaN)
   - VXISI (if Infinity – Infinity)
   - VXIDI (if Infinity ÷ Infinity)
   - VXZDZ (if Zero ÷ Zero)
   - VXIMZ (if Infinity × Zero)
   - VXSQRT (if Invalid Square Root)

2. The single-precision representation of a Quiet NaN is placed into its respective word element of VSR[XT].

3. FR, FI, and FPRF are not modified.

For the VSX Scalar Double-Precision Arithmetic instructions, VSX Scalar Double-Precision Maximum/Minimum instructions, the VSX Scalar Convert Single-Precision to Double-Precision format (xscvsdpd) instruction, and the VSX Scalar Round to Double-Precision Integer instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.
   - VXSNAN (if SNaN)
   - VXISI (if Infinity – Infinity)
   - VXIDI (if Infinity ÷ Infinity)
   - VXZDZ (if Zero ÷ Zero)
   - VXIMZ (if Infinity × Zero)
   - VXSQRT (if Invalid Square Root)

2. The double-precision representation of a Quiet NaN is placed into doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are undefined.

3. FR and FI are set to 0.

4. FPRF is set to indicate the class of the result (Quiet NaN).

For the VSX Vector Double-Precision Arithmetic instructions, VSX Vector Double-Precision Maximum/Minimum instructions, the VSX Vector Convert Single-Precision to Double-Precision format (xvcvsdpd) instruction, and the VSX Vector Round to Double-Precision Integer instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.
   - VXSNAN (if SNaN)
   - VXISI (if Infinity – Infinity)
   - VXIDI (if Infinity ÷ Infinity)
   - VXZDZ (if Zero ÷ Zero)
   - VXIMZ (if Infinity × Zero)
   - VXSQRT (if Invalid Square Root)

2. The double-precision representation of a Quiet NaN is placed into its respective doubleword element of VSR[XT].

3. FR, FI, and FPRF are not modified.
For the **VSX Scalar Convert Double-Precision to Signed Integer Doubleword** (**xscvdpsxd**) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN  (if SNaN)
   VXCVI   (if Invalid Integer Convert)

2. 0x7FFF_FFFF_FFFF_FFFF is placed into doubleword element 0 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a positive number or +Infinity.

   0x8000_0000_0000_0000 is placed into doubleword element 0 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a negative number, -Infinity, or NaN.

   The contents of doubleword element 1 of VSR[XT] are undefined.

3. FR and FI are set to 0.

4. FPRF is undefined.

For the **VSX Scalar Convert Double-Precision to Signed Integer Word** (**xscvdpsxw**) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN  (if SNaN)
   VXCVI   (if Invalid Integer Convert)

2. 0x7FFF_FFFF is placed into word element 1 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a positive number or +Infinity.

   0x8000_0000 is placed into word element 1 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a negative number, -Infinity, or NaN.

   The contents of word elements 0, 2, and 3 of VSR[XT] are undefined.

3. FR and FI are set to 0.

4. FPRF is undefined.

For the **VSX Scalar Convert Double-Precision to Unsigned Integer Doubleword** (**xscvdpuxd**) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN  (if SNaN)
   VXCVI   (if Invalid Integer Convert)

2. 0xFFFF_FFFF_FFFF_FFFF is placed into doubleword element 0 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a positive number or +Infinity.

   0x0000_0000_0000_0000 is placed into doubleword element 0 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a negative number, -Infinity, or NaN.

   The contents of doubleword element 1 of VSR[XT] are undefined.

3. FR and FI are set to 0.

4. FPRF is undefined.

For the **VSX Scalar Convert Double-Precision to Unsigned Integer Word** (**xscvdpuxw**) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN  (if SNaN)
   VXCVI   (if Invalid Integer Convert)

2. 0xFFFF_FFFF is placed into word element 1 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a positive number or +Infinity.

   0x0000_0000 is placed into word element 1 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a negative number, -Infinity, or NaN.

   The contents of word elements 0, 2, and 3 of VSR[XT] are undefined.

3. FR and FI are set to 0.

4. FPRF is undefined.
For the VSX Vector Convert Double-Precision to Signed Integer Doubleword (xvcvdpsxd) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN (if SNaN)
   VXCVI (if Invalid Integer Convert)

2. \(0x7FFF_FFFF_FFFF_FFFF\) is placed into doubleword element i of VSR[XT] if the double-precision operand in the corresponding doubleword element of VSR[XB] is a positive number or +Infinity.

   \(0x8000_0000_0000_0000\) is placed into its respective doubleword element i of VSR[XT] if the double-precision operand in the corresponding doubleword element of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the VSX Vector Convert Double-Precision to Unsigned Integer Doubleword (xvcvdpuxd) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN (if SNaN)
   VXCVI (if Invalid Integer Convert)

2. \(0xFFFF_FFFF_FFFF_FFFF\) is placed into doubleword element i of VSR[XT] if the double-precision operand in doubleword element i of VSR[XB] is a positive number or +Infinity.

   \(0x0000_0000_0000_0000\) is placed into doubleword element i of VSR[XT] if the double-precision operand in doubleword element i of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the VSX Vector Convert Double-Precision to Signed Integer Word (xvcvdpsxw) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN (if SNaN)
   VXCVI (if Invalid Integer Convert)

2. \(0x7FFF_FFFF\) is placed into word element \(i\times2\) of VSR[XT] if the double-precision operand in doubleword element i of VSR[XB] is a positive number or +Infinity.

   \(0x8000_0000\) is placed into word element \(i\times2+1\) of VSR[XT] if the double-precision operand in doubleword element i of VSR[XB] is a negative number, -Infinity, or NaN.

   The contents of word element \(i\times2+1\) of VSR[XT] are undefined.

3. FR, FI, and FPRF are not modified.

For the VSX Vector Convert Double-Precision to Unsigned Integer Word (xvcvdpuxw) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN (if SNaN)
   VXCVI (if Invalid Integer Convert)

2. \(0xFFFF_FFFF\) is placed into word element \(i\times2\) of VSR[XT] if the double-precision operand in doubleword element i of VSR[XB] is a positive number or +Infinity.

   \(0x0000_0000\) is placed into word element \(i\times2\) of VSR[XT] if the double-precision operand in doubleword element i of VSR[XB] is a negative number, -Infinity, or NaN.

   The contents of word element \(i\times2+1\) of VSR[XT] are undefined.

3. FR, FI, and FPRF are not modified.

For the VSX Vector Convert Single-Precision to Signed Integer Doubleword (xvcvspsxd) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN (if SNaN)
   VXCVI (if Invalid Integer Convert)

2. \(0x7FFF_FFFF_FFFF_FFFF\) is placed into doubleword element i of VSR[XT] if the single-precision operand in word element \(i\times2\) of VSR[XB] is a positive number or +Infinity.

   \(0x8000_0000_0000_0000\) is placed into doubleword element i of VSR[XT] if the single-precision operand in word element \(i\times2\) of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.
For the VSX Vector Convert Single-Precision to
Unsigned Integer Doubleword (**xvcvspuxd**) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.
   - VXSNAN (if SNaN)
   - VXCVI (if Invalid Integer Convert)

2. **0xFFFF_FFFF_FFFF_FFFF** is placed into doubleword element i of VSR[XT] if the single-precision operand in word element i×2 of VSR[XB] is a positive number or +Infinity.
   - **0x0000_0000_0000_0000** is placed into doubleword element i of VSR[XT] if the single-precision operand in word element i×2 of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the VSX Vector Convert Single-Precision to
Signed Integer Word (**xvcvspsxw**) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.
   - VXSNAN (if SNaN)
   - VXCVI (if Invalid Integer Convert)

2. **0x7FFF_FFFF** is placed into word element i of VSR[XT] if the single-precision operand in word element i of VSR[XB] is a positive number or +Infinity.
   - **0x8000_0000** is placed into word element i of VSR[XT] if the single-precision operand in word element i of VSR[XB] is a negative number, -Infinity, or NaN.
   - The contents of word element i×2+1 of VSR[XT] are undefined.

3. FR, FI, and FPRF are not modified.

For the VSX Vector Convert Single-Precision to
Unsigned Integer Word (**xvcvspuxw**) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.
   - VXSNAN (if SNaN)
   - VXCVI (if Invalid Integer Convert)

2. **0xFFFF_FFFF** is placed into word element i of VSR[XT] if the single-precision operand in the corresponding word element i×2 of VSR[XB] is a positive number or +Infinity.
   - **0x0000_0000** is placed into word element i of VSR[XT] if the single-precision operand in word element i×2 of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the VSX Vector Convert Single-Precision to
Signed Integer Word (**xvcvspsxw**) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.
   - VXSNAN (if SNaN)
   - VXCVI (if Invalid Integer Convert)

2. **0x7FFFFFFF** is placed into word element i of VSR[XT] if the single-precision operand in word element i×2 of VSR[XB] is a positive number or +Infinity.
   - **0x8000_0000** is placed into word element i of VSR[XT] if the single-precision operand in word element i×2 of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the VSX Scalar Floating-Point Compare instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.
   - VXSNAN (if SNaN)
   - VXCVI (if Invalid Integer Convert)

2. **0x0000_0000** is placed into its respective word element of VSR[XT].

3. FR, FI, and FPRF are not modified.

For the VSX Vector Compare Single-Precision instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.
   - VXSNAN (if SNaN)
   - VXCVI (if Invalid Integer Convert)

2. **0x0000_0000** is placed into its respective word element of VSR[XT].

3. FR, FI, and FPRF are not modified.
For the vector double-precision compare instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   \[\text{VXSNAN} \quad (\text{if SNaN})\]
   \[\text{VXCVI} \quad (\text{if Invalid Integer Convert})\]

2. 0x0000_0000_0000_0000 is placed into its respective doubleword element of VSR[XT].

3. FR, FI, and FPRF are not modified.
Chapter 7. Vector-Scalar Floating-Point Operations [Category: VSX]

7.4.2 Floating-Point Zero Divide Exception

7.4.2.1 Definition

A Zero Divide exception occurs when a VSX Floating-Point Divide instruction is executed with a zero divisor value and a finite nonzero dividend value. A Zero Divide exception also occurs when a VSX Floating-Point Reciprocal Estimate instruction or a VSX Floating-Point Reciprocal Square Root Estimate instruction is executed with an operand value of zero.

The action to be taken depends on the setting of the Zero Divide Exception Enable bit of the FPSCR.

7.4.2.2 Action for ZE=1

When Zero Divide exception is enabled (ZE=1) and a Zero Divide exception occurs, the following actions are taken:

For VSX Scalar Floating-Point Divide instructions, VSX Scalar Floating-Point Reciprocal Estimate instructions, and VSX Scalar Floating-Point Reciprocal Square Root Estimate instructions, do the following.

1. ZX is set to 1.
2. Update of VSR[XT] is suppressed.
3. FR and FI are set to 0.
4. FPRF is unchanged.

For VSX Vector Floating-Point Divide instructions, VSX Vector Floating-Point Reciprocal Estimate instructions, and VSX Vector Floating-Point Reciprocal Square Root Estimate instructions, do the following.

1. ZX is set to 1.
2. Update of VSR[XT] is suppressed for all vector elements.
3. FR and FI are unchanged.
4. FPRF is unchanged.

1. VSX Floating-Point Divide instructions:
   - xsdivdp, xsdivsp, xvdivdp, xvdivsp
2. VSX Floating-Point Reciprocal Estimate instructions:
   - xsredp, xsresp, xvredp, xvresp
3. VSX Floating-Point Reciprocal Square Root Estimate instructions:
   - xsrsqrtedp, xsrsqrtesp, xvsqrtedp, xvsqrtresp
4. VSX Scalar Floating-Point Divide instructions:
   - xsdivdp, xsdivsp
5. VSX Scalar Floating-Point Reciprocal Estimate instructions:
   - xsredp, xsresp
6. VSX Scalar Floating-Point Reciprocal Square Root Estimate instructions:
   - xsrsqrtedp, xsrsqrtesp
7. VSX Vector Floating-Point Divide instructions:
   - xvdivdp, xvdivsp
8. VSX Vector Floating-Point Reciprocal Estimate instructions:
   - xvredp, xvresp
9. VSX Vector Floating-Point Reciprocal Square Root Estimate instructions:
   - xvsqrtedp, xvsqrtresp
7.4.2.3 Action for ZE=0

When Zero Divide exception is disabled (ZE=0) and a Zero Divide exception occurs, the following actions are taken:

For VSX Scalar Floating-Point Divide\[1\] instructions, do the following.

1. ZX is set to 1.
2. An Infinity, having a sign determined by the XOR of the signs of the source operands, is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are undefined.
3. FR and FI are set to 0.
4. FPRF is set to indicate the class and sign of the result (± Infinity).

For VSX Vector Divide Double-Precision \(\text{xvdivdp}\), do the following.

1.ZX is set to 1.
2. For each vector element causing a Zero Divide exception, an Infinity, having a sign determined by the XOR of the signs of the source operands, is placed into its respective doubleword element of VSR[XT] in double-precision format.
3. FR, FI, and FPRF are not modified.

For VSX Vector Divide Single-Precision \(\text{xvdivsp}\), do the following.

1. ZX is set to 1.
2. For each vector element causing a Zero Divide exception, an Infinity, having a sign determined by the XOR of the signs of the source operands, is placed into its respective word element of VSR[XT] in single-precision format.
3. FR, FI, and FPRF are not modified.

For VSX Scalar Floating-Point Reciprocal Estimate\[2\] instructions and VSX Scalar Floating-Point Reciprocal Square Root Estimate\[3\] instructions, do the following.

1. ZX is set to 1.
2. An Infinity, having the sign of the source operand, is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are undefined.
3. FR and FI are set to 0.
4. FPRF is set to indicate the class and sign of the result (± Infinity).

For the VSX Vector Reciprocal Estimate Double-Precision \(\text{xvredp}\) and VSX Vector Reciprocal Square Root Estimate Double-Precision \(\text{xvrsqrtedp}\) instructions:

1. ZX is set to 1.
2. For each vector element causing a Zero Divide exception, an Infinity, having the sign of the source operand, is placed into its respective doubleword element of VSR[XT] in double-precision format.
3. FR, FI, and FPRF are not modified.

For the VSX Vector Reciprocal Estimate Single-Precision \(\text{xvresp}\) and VSX Vector Reciprocal Square Root Estimate Single-Precision \(\text{xvrsqrtesp}\) instructions:

1. ZX is set to 1.
2. For each vector element causing a Zero Divide exception, an Infinity, having the sign of the source operand, is placed into its respective word element of VSR[XT] in single-precision format.
3. FR, FI, and FPRF are not modified.

1. VSX Scalar Floating-Point Divide instructions: \(\text{xsdvdp, xsdivsp}\)
2. VSX Scalar Floating-Point Reciprocal Estimate instructions: \(\text{xrsrdp, xsrsesp}\)
3. VSX Scalar Floating-Point Reciprocal Square Root Estimate instructions: \(\text{xrsqrtedp, xsrqsqrtresp}\)
7.4.3 Floating-Point Overflow Exception

7.4.3.1 Definition

An Overflow exception occurs when the magnitude of what would have been the rounded result if the exponent range were unbounded exceeds that of the largest finite number of the specified result precision.

The action to be taken depends on the setting of the Overflow Exception Enable bit of the FPSR.

7.4.3.2 Action for OE=1

When Overflow exception is enabled (OE=1) and an Overflow exception occurs, the following actions are taken:

For the VSX Vector round and Convert Double-Precision to Single-Precision format (xscvdpsp) instruction:

1. OX is set to 1.
2. If the unbiased exponent of the normalized intermediate result is less than or equal to 318 (Emax+192), the exponent is adjusted by subtracting 192. Otherwise the result is undefined.
3. The adjusted rounded result is placed into word element 0 of VSR[XT] in single-precision format. The contents of word elements 1-3 of VSR[XT] are undefined.
4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result (±Normal Number).

For VSX Scalar Double-Precision Arithmetic\(^1\) instructions, do the following.

1. OX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by subtracting 1536.
3. The adjusted rounded result is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are undefined.
4. FPRF is set to indicate the class and sign of the result (±Normal Number).

For VSX Scalar Single-Precision Arithmetic\(^2\) instructions, do the following.

1. OX is set to 1.
2. The exponent is adjusted by subtracting 192.
3. The adjusted and rounded result is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are undefined.
4. FPRF is set to indicate the class and sign of the result (±Normal Number).

For VSX Vector Double-Precision Arithmetic\(^3\) instructions, VSX Vector Single-Precision Arithmetic\(^4\) instructions, and VSX Vector round and Convert Double-Precision to Single-Precision format instruction (xvcvdpsp), do the following.

1. OX is set to 1.
2. Update of VSR[XT] is suppressed for all vector elements.
3. FR, FI, and FPRF are not modified.

---

1. VSX Scalar Double-Precision Arithmetic instructions:
   - xsadddp, xsdvdp, xsmuldp, xsredp, xssubdp, xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp, xsnmaddadp, xsnmaddmdp, xsnmsubadp, xsnmsubmdp

2. VSX Scalar Single-Precision Arithmetic instructions:
   - xsaddsp, xsdivsp, xsmulsp, xssresp, xssubsp, xsmaddasp, xsmaddmsp, xsmsubasp, xsmsubmsp, xsnmaddasp, xsnmaddmsp, xsnmsubasp, xsnmsubmsp

3. VSX Vector Double-Precision Arithmetic instructions:
   - xvadddp, xvdvdp, xvmuldp, xvredp, xvsbmdp, xvmaddadp, xvmaddmdp, xvmsubadp, xvmsubmdp, xvmnmaddadp, xvmnmaddmdp, xvmnmsubadp, xvmnmsubmdp

4. VSX Vector Single-Precision Arithmetic instructions:
   - xvaddsp, xvdvsp, xvmulsp, xvresp, xvsbsp, xvmaddasp, xvmaddmsp, xvmsubasp, xvmsubmsp, xvmnmaddasp, xvmnmaddmsp, xvmnmsubasp, xvmnmsubmsp
7.4.3.3 Action for OE=0

When Overflow exception is disabled (OE=0) and an Overflow exception occurs, the following actions are taken:

1. OX and XX are set to 1.

2. The result is determined by the rounding mode (RN) and the sign of the intermediate result as follows:

   **Round to Nearest Even**
   
   For negative overflow, the result is $-\infty$.
   
   For positive overflow, the result is $+\infty$.

   **Round toward Zero**
   
   For negative overflow, the result is the format's most negative finite number.
   
   For positive overflow, the result is the format's most positive finite number.

   **Round toward $+\infty$**
   
   For negative overflow, the result is the format's most negative finite number.
   
   For positive overflow, the result is $+\infty$.

   **Round toward $-\infty$**
   
   For negative overflow, the result is $-\infty$.
   
   For positive overflow, the result is the format's most positive finite number.

3. The result is placed into word element 0 of VSR[XT] as a single-precision value. The contents of word elements 1-3 of VSR[XT] are undefined.

4. FR is undefined.

5. Fi is set to 1.

6. FPRF is set to indicate the class and sign of the result.

For VSX Scalar Double-Precision Arithmetic\(^1\) instructions and VSX Scalar Single-Precision Arithmetic\(^2\) instructions, do the following.

3. The result is placed into doubleword element 0 of VSR[XT] as a double-precision value. The contents of doubleword element 1 of VSR[XT] are undefined.

4. FR is undefined.

5. Fi is set to 1.

6. FPRF is set to indicate the class and sign of the result.

For VSX Vector Double-Precision Arithmetic\(^3\) instructions, do the following.

3. For each vector element causing an Overflow exception, the result is placed into its respective doubleword element of VSR[XT] in double-precision format.

4. FR, Fi, and FPRF are not modified.

For VSX Vector Single-Precision Arithmetic\(^4\) instructions and VSX Vector round and Convert Double-Precision to Single-Precision format (\texttt{xvcvdpsp}), do the following.

3. For each vector element causing an Overflow exception, the result is placed into its respective word element of VSR[XT] in single-precision format.

4. FR, Fi, and FPRF are not modified.

---

1. VSX Scalar Double-Precision Arithmetic instructions:
   \texttt{xsadddp, xsdivdp, xsmuldp, xsmredp, xssubdp, xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp, xsnaddddp, xsnaddmdp, xsnsubadp, xsnsubmdp}

2. VSX Scalar Single-Precision Arithmetic instructions:
   \texttt{xsaddsp, xsdivsp, xsmulsp, xsmresp, xsresp, xssubsp, xsmaddasp, xsmaddmsp, xsmsubasp, xsmsubmsp, xsnaddadsp, xsnaddmdsp, xsnsubadsp, xsnsubmdsp}

3. VSX Vector Double-Precision Arithmetic instructions:
   \texttt{xvadddp, xvdivdp, xvmuldp, xvredp, xsresvp, xsvsubvp, xvmaddadp, xvmaddmdp, xvmsubadp, xvmsubmdp, xvmnaddadp, xvmnaddmdp, xvmnsubadp, xvmnsubmdp}

4. VSX Vector Single-Precision Arithmetic instructions:
   \texttt{xvaddsp, xvdivsp, xvmulsp, xvresp, xsvsubsp, xvmaddasp, xvmaddmsp, xvmsubasp, xvmsubmsp, xvmnaddasp, xvmnaddmsp, xvmnsubasp, xvmnsubmsp}
Chapter 7. Vector-Scalar Floating-Point Operations [Category: VSX]

7.4.4 Floating-Point Underflow Exception

7.4.4.1 Definition

Underflow exception is defined separately for the enabled and disabled states:

**Enabled:**
Underflow occurs when the intermediate result is "Tiny".

**Disabled:**
Underflow occurs when the intermediate result is "Tiny" and there is "Loss of Accuracy".

A tiny result is detected before rounding, when a nonzero intermediate result computed as though both the precision and the exponent range were unbounded would be less in magnitude than the smallest normalized number.

If the intermediate result is tiny and Underflow exception is disabled (UE=0), the intermediate result is denormalized (see Section 7.3.2.4, "Normalization and Denormalization" on page 331) and rounded (see Section 7.3.2.6, "Rounding" on page 335) before being placed into the target VSR.

Loss of accuracy is detected when the delivered result value differs from what would have been computed were both the precision and the exponent range unbounded.

The action to be taken depends on the setting of the Underflow Exception Enable bit of the FPSCR.

7.4.4.2 Action for UE=1

When Underflow exception is enabled (UE=1) and an Underflow exception occurs, the following actions are taken:

For VSX Scalar round and Convert Double-Precision to Single-Precision format (xscvdpsp), do the following.
1. UX is set to 1.
2. If the unbiased exponent of the normalized intermediate result is greater than or equal to -319 (Emin-192), the exponent is adjusted by adding 192. Otherwise the result is undefined.
3. The adjusted rounded result is placed into word element 0 of VSR[XT] in single-precision format. The contents of word elements 1-3 of VSR[XT] are undefined.
4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result (±Normal Number).

For VSX Scalar Double-Precision Arithmetic\(^1\) instructions and VSX Scalar Double-Precision Reciprocal Estimate (xsredp), do the following.
1. UX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 1536.
3. The adjusted rounded result is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are undefined.
4. FPRF is set to indicate the class and sign of the result (±Normal Number).

---

\(^1\) VSX Scalar Double-Precision Arithmetic instructions: xsaddp, xsdivdp, xsmuld, xssubdp, xsmadddp, xsmaddmdp, xsmsubadp, xsmsubmdp, xsnmadddp, xsnmaddmdp, xsnmsubadp, xsnmsubmdp
For VSX Scalar Single-Precision Arithmetic\(^1\) instructions and VSX Scalar Single-Precision Reciprocal Estimate (\texttt{xsresp})

1. UX is set to 1.

2. The exponent is adjusted by adding 192.

3. The adjusted rounded result is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are undefined.

4. FPRF is set to indicate the class and sign of the result (\pm Normal Number).

### Programming Note

The FR and FI bits are provided to allow the system floating-point enabled exception error handler, when invoked because of an Underflow exception, to simulate a "trap disabled" environment. That is, the FR and FI bits allow the system floating-point enabled exception error handler to unround the result, thus allowing the result to be denormalized and correctly rounded.

For VSX Vector Floating-Point Arithmetic\(^2\) instructions, VSX Vector Floating-Point Reciprocal Estimate\(^3\) instructions, and VSX Vector round and Convert Double-Precision to Single-Precision format (\texttt{xvcvdpsp}), do the following:

1. UX is set to 1.

2. Update of VSR[XT] is suppressed for all vector elements.

3. FR, FI, and FPRF are not modified.

### 7.4.4.3 Action for UE=0

When Underflow exception is disabled (UE=0) and an Underflow exception occurs, the following actions are taken:

For VSX Scalar round and Convert Double-Precision to Single-Precision format (\texttt{xscvdpsp})

1. UX is set to 1.

2. The result is placed into word element 0 of VSR[XT] in single-precision format. The contents of word elements 1-3 of VSR[XT] are undefined.

3. FPRF is set to indicate the class and sign of the result.

For VSX Scalar Floating-Point Arithmetic\(^4\) instructions and VSX Scalar Reciprocal Estimate\(^5\) instructions, do the following:

1. UX is set to 1.

2. The result is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are undefined.

3. FPRF is set to indicate the class and sign of the result.

For VSX Vector Double-Precision Arithmetic\(^6\) instructions and VSX Vector Reciprocal Estimate Double-Precision (\texttt{xvredp})

1. UX is set to 1.

2. For each vector element causing an Underflow exception, the result is placed into its respective doubleword element of VSR[XT] in double-precision format.

3. FR, FI, and FPRF are not modified.

---

1. VSX Scalar Single-Precision Arithmetic instructions: \texttt{xsdssp}, \texttt{xsdvssp}, \texttt{xsmulp}, \texttt{xssubp}, \texttt{xsmaddsp}, \texttt{xsmaddmsp}, \texttt{xmsubasp}, \texttt{xmsubmsp}, \texttt{xsmaddasp}, \texttt{xsmaddmsp}, \texttt{xsnmsubasp}, \texttt{xsnmsubmsp}

2. VSX Vector Arithmetic instructions: \texttt{xvdssp}, \texttt{xvdvdp}, \texttt{xvmulp}, \texttt{xsvsubdp}, \texttt{xsvadsp}, \texttt{xsvdivsp}, \texttt{xsvmlsp}, \texttt{xsvsubp}, \texttt{xsvmaddsp}, \texttt{xsvmadddp}, \texttt{vxvsubdpp}, \texttt{vxvsubdmdp}, \texttt{vxvmaddsp}, \texttt{vxvmadddp}, \texttt{vxvmsubdp}, \texttt{vxvmsubdpp}, \texttt{vxvmsubasp}, \texttt{vxvmsubmsp}, \texttt{vxvmaddasp}, \texttt{vxvmadddmp}, \texttt{vxvmsubdsp}, \texttt{vxvmsubdmp}, \texttt{vxvmsubasp}, \texttt{vxvmsubmsp}

3. VSX Vector Floating-Point Reciprocal Estimate instructions: \texttt{xvredp}, \texttt{xvresp}

4. VSX Scalar Floating-Point Arithmetic instructions: \texttt{xvdssp}, \texttt{xvdvdp}, \texttt{xvmulp}, \texttt{xsvsubdp}, \texttt{xsvadsp}, \texttt{xsvdivsp}, \texttt{xsvmlsp}, \texttt{xsvsubp}, \texttt{xsvmaddsp}, \texttt{xsvmadddp}, \texttt{vxvsubdpp}, \texttt{vxvsubdmdp}, \texttt{vxvmaddsp}, \texttt{vxvmadddp}, \texttt{vxvmsubdp}, \texttt{vxvmsubdpp}, \texttt{vxvmsubasp}, \texttt{vxvmsubmsp}

5. VSX Scalar Reciprocal Estimate instructions: \texttt{xvredp}, \texttt{xvresp}

6. VSX Vector Double-Precision Arithmetic instructions: \texttt{xvdssp}, \texttt{xvdvdp}, \texttt{xvmulp}, \texttt{xsvsubdp}, \texttt{xsvadsp}, \texttt{xsvmaddsp}, \texttt{xsvmadddp}, \texttt{vxvsubdpp}, \texttt{vxvsubdmdp}, \texttt{vxvmaddsp}, \texttt{vxvmadddmp}, \texttt{vxvmsubdsp}, \texttt{vxvmsubdmp}, \texttt{vxvmsubasp}, \texttt{vxvmsubmsp}
For VSX Vector Single-Precision Arithmetic\(^1\) instructions, VSX Vector Reciprocal Estimate Single-Precision (\texttt{xvresp}), and VSX Vector round and Convert Double-Precision to Single-Precision format (\texttt{xvcvdpsp}), do the following.

1. UX is set to 1.

2. For each vector element causing an Underflow exception, the result is placed into its respective word element of VSR[XT] in single-precision format.

3. FR, FI, and FPRF are not modified.

---

\(^1\) VSX Vector Single-Precision Arithmetic instructions:
\texttt{xvaddsp, xvdvsp, xvmlsp, xvsbasp, xvmaddsp, xvmaddmsp, xvmsubasp, xvmsubbasp, xvmaddasp, xvmaddmssp, xvmmsubasp, xvmmsubbasp}
7.4.5 Floating-Point Inexact Exception

7.4.5.1 Definition

An Inexact exception occurs when one of two conditions occur during rounding:

1. The rounded result differs from the intermediate result assuming both the precision and the exponent range of the intermediate result to be unbounded. In this case the result is said to be inexact. (If the rounding causes an enabled Overflow exception or an enabled Underflow exception, an Inexact exception also occurs only if the significands of the rounded result and the intermediate result differ.)

2. The rounded result overflows and Overflow exception is disabled.

The action to be taken depends on the setting of the Inexact Exception Enable bit of the FPSCR.

7.4.5.2 Action for XE=1

When Inexact exception is enabled (UE=1) and an Inexact exception occurs, the following actions are taken:

For the VSX Vector round and Convert Double-Precision to Single-Precision format (xscvdpsp) instruction:

1. XX is set to 1.
2. The result is placed into word element 0 of VSR[XT] in single-precision format. The contents of word elements 1-3 of VSR[XT] are undefined.
3. FPRF is set to indicate the class and sign of the result.

For the VSX Scalar Floating-Point Arithmetic instructions:
- xsaddp, xsdivp, xsmulp, xssubp, xsmaddp, xsmaddsp, xsmsubp, xsmsubsp, xsnmaddp, xsnmaddsp, xsnmsubp, xsnmsubsp, xsnmadddp, xsnmaddsp, xsnmsubdp, xsnmsubsp, xsmaddmp, xsmaddsp, xsmsubmp, xsmsubsp, xsnmaddmp, xsnmaddsp, xsnmsubmp, xsnmsubsp

- For VSX Scalar Floating-Point Reciprocal Estimate instructions:
- xsvcpp, xsvcvmpp, xsvcppsp, xsvcvmppsp

- For VSX Vector Floating-Point Arithmetic instructions:
- xvadddp, xvdivdp, xvmpdp, xvsubdp, xsaddsp, xvdivsp, xvmulp, xvsubsp, xsmaddsp, xsmaddmp, xsmaddsp, xsmsubsp, xsnmaddsp, xsnmaddmp, xsnmsubsp, xsnmaddsp, xsnmaddmp, xsnmaddsp, xsnmsubsp, xsnmaddsp

1. VSX Scalar Floating-Point Arithmetic instructions:
   - xsaddp, xsdivp, xsmulp, xssubp, xsmaddp, xsmaddsp, xsmsubp, xsmsubsp, xsnmaddp, xsnmaddsp, xsnmsubp, xsnmsubsp, xsmaddmp, xsmaddsp, xsmsubmp, xsmsubsp, xsnmaddmp, xsnmaddsp, xsnmsubmp, xsnmsubsp

2. VSX Vector Integer to Floating-Point Format Conversion instructions:
   - xsvcpp, xsvcppsp, xsvcppmp, xsvcppmpsp

3. VSX Vector Floating-Point to Integer Word Format Conversion instructions:
   - xsvcpp, xsvcppws, xsvcppwsp

4. VSX Vector Floating-Point Arithmetic instructions:
   - xvaddp, xvdivp, xvmulp, xvsubp, xsaddp, xvdivp, xvmulp, xvsubp, xsmaddp, xsmaddsp, xsmsubp, xsnmaddp, xsnmaddsp, xsnmsubp, xsnmaddsp, xsnmaddmp, xsnmaddsp, xsnmsubmp, xsnmsubsp, xsnmaddsp, xsnmaddmp, xsnmaddsp, xsnmsubmp, xsnmsubsp
7.4.5.3 Action for XE=0

When Inexact exception is disabled (XE=0) and an Inexact exception occurs, the following actions are taken:

For **VSX Scalar round and Convert Double-Precision to Single-Precision format (xscvdpsp)**, do the following.

1. XX is set to 1.
2. The result is placed into word element 0 of VSR[XT] as a single-precision value. The contents of word elements 1-3 of VSR[XT] are undefined.
3. FPRF is set to indicate the class and sign of the result.

For **VSX Scalar Double-Precision Arithmetic** instructions, **VSX Scalar Single-Precision Arithmetic** instructions, **VSX Scalar Round to Single-Precision (xsrsp)**, the **VSX Scalar Round to Double-Precision Integer Exact using Current rounding mode (xsrdpic)**, and **VSX Scalar Round to Double-Precision Format Conversion** instructions, do the following.

1. XX is set to 1.
2. The result is placed into doubleword element 0 of VSR[XT] as a double-precision value. The contents of doubleword element 1 of VSR[XT] are undefined.
3. FPRF is set to indicate the class and sign of the result.

For **VSX Scalar Convert Double-Precision To Integer Word format with Saturate** instructions, do the following.

1. XX is set to 1.
2. The result is placed into word element 1 of VSR[XT]. The contents of word elements 0, 2, and 3 of VSR[XT] are undefined.
3. FPRF is set to indicate the class and sign of the result.

For **VSX Vector Double-Precision Arithmetic** instructions, do the following.

1. XX is set to 1.
2. For each vector element causing an Inexact exception, the result is placed into its respective doubleword element of VSR[XT] in double-precision format.
3. FR, FI, and FPRF are not modified.

For **VSX Vector Single-Precision Arithmetic** instructions, do the following.

1. XX is set to 1.
2. For each vector element causing an Inexact exception, the result is placed into its respective word element of VSR[XT] in single-precision format.
3. FR, FI, and FPRF are not modified.

5. **VSX Vector Floating-Point Reciprocal Estimate instructions**: xvredp, xvresp
6. **VSX Vector Double-Precision to Integer Format Conversion instructions**: xvcvdpsdxds, xvcvdpsxws, xvcvdpxdpsxds, xvcvdpxwxs
7. **VSX Vector Integer to Floating-Point Format Conversion instructions**: xvcvsxdp, xvcvsxdsp, xvcvsxdsdxsp, xvcvsxdsxwsp, xvcvsxwsp, xvcvxwsp
1. **VSX Scalar Double-Precision Arithmetic instructions**: xsaddp, xssubdp, xsmdulp, xsdivdp, xssqrtsp, xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp, xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp
2. **VSX Scalar Single-Precision Arithmetic instructions**: xsaddsp, xssubsp, xsmulp, xsdivsp, xssqrtsp, xsmaddsp, xsmaddmssp, xsmsubasp, xsmsubmsp, xsmaddasp, xsmaddmssp, xsmsubasp, xsmsubmsp
3. **VSX Scalar Integer to Double-Precision Format Conversion instructions**: xscvsxdp, xscvuxdp
4. **VSX Scalar Convert Double-Precision To Integer Word format with Saturate instructions**: xscvdpsdxds, xscvdpsxws, xscvdpxdpsxds, xscvdpxwxs
5. **VSX Vector Double-Precision Arithmetic instructions**: xsaddp, xssubdp, xsmdulp, xsdivdp, xssqrtsp, xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp, xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp
6. **VSX Vector Single-Precision Arithmetic instructions**: xvaddsp, xsvsubsp, xsvmulsp, xsvdivsp, xsvsqrstsp, xsvmaddsp, xsvmaddmssp, xsvmsubasp, xsvmsubmsp, xsvmaddasp, xsvmaddmssp, xsvmsubasp, xsvmsubmsp

Chapter 7. Vector-Scalar Floating-Point Operations [Category: VSX] 357
7.5 VSX Storage Access Operations

The VSX Storage Access instructions compute the effective address (EA) of the storage to be accessed as described in Power ISA Book I.

7.5.1 Accessing Aligned Storage Operands

The following quadword-aligned array, AH, consists of 8 halfwords.

```c
short AW[4] = { 0x0001_0203,
    0x0405_0607,
    0x0809_0A0B,
    0x0C0D_0E0F };
```

Figure 119 illustrates the big-endian storage image of array AW.

![Big-endian storage image of array AW](image1)

Figure 120 illustrates the little-endian storage image of array AW.

![Little-endian storage image of array AW](image2)

Figure 121 shows the result of loading that quadword into a VSR or, equivalently, shows the contents that must be in a VSR if storing that VSR is to produce the storage contents shown in Figure 119 for big-endian. Note that Figure shows the effect of loading the quadword from both big-endian storage and little-endian storage.

![Vector-Scalar Register contents for aligned quadword Load or Store VSX Vector](image3)
7.5.2 Accessing Unaligned Storage Operands

The following array, B, consists of 5 word elements.

```c
int B[5];
B[0] = 0x01234567;
B[1] = 0x00112233;
B[2] = 0x44556677;
B[3] = 0x8899AABB;
B[4] = 0xCCDDEEFF;
```

Figure 122 illustrates both big-endian and little-endian storage images of array B.

### Loading an Unaligned Quadword from Big-Endian Storage

Loading elements from elements 1 through 4 of B (see Figure 122) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using big-endian byte ordering.

### Loading an Unaligned Quadword from Little-Endian Storage

Loading elements from elements 1 through 4 of B (see Figure 122) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using little-endian byte ordering.

---

**# Assumptions**

- GPR[Ra] = address of B
- GPR[Rb] = 4 (index to B[1])

- lxvw4x Xt,Ra,Rb

```
Xt: 00 11 22 33 44 55 66 77 88 99 AABBCCDDEEFF
```

**Figure 123. Process to load misaligned quadword from big-endian storage using Load VSX Vector Word*4 Indexed**

---

**# Assumptions**

- GPR[A] = address of B
- GPR[B] = 4 (index to B[1])

- lxvw4x Xt,Ra,Rb

```
Xt: 00 11 22 33 44 55 66 77 88 99 AABBCCDDEEFF
```

**Figure 124. Process to load misaligned quadword from little-endian storage Load VSX Vector Word*4 Indexed**
Storing an Unaligned Quadword to Big-Endian Storage

Storing a VSR to elements 1 through 4 of B (see Figure 122) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using big-endian byte ordering.

### Big-endian storage image of array B

| 0x0000: | 01234567 | 00112233 | 44556677 | 8899AABB |
| 0x0010: | CC DDEE FF | 01234567 | 8899AABB | F0F1F2F3 |

### Big-endian storage image of array B

| 0x0000: | 01234567F0F1F2F3F4F5F6F7 |
| 0x0010: | FCFDFEFF |

**# Assumptions**

GPR[Ra] = address of B

GPR[Rb] = 4 \[\text{index to B}[-1]\]

```stxvw4x Xs,Ra,Rb```

**Figure 125. Process to store misaligned quadword to big-endian storage using Store VSX Vector Word*4 Indexed**

Storing an Unaligned Quadword to Little-Endian Storage

Storing a VSR to elements 1 through 4 of B (see Figure 122) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using little-endian byte ordering.

### Little-endian storage image of array B

| 0x0000: | 6745230133221100 |
| 0x0010: | 77665544BB AAA988 |

### Little-endian storage image of array B

| 0x0000: | 00123456789AB CDEF |
| 0x0010: | 0123456789AB CDEF |

**# Assumptions**

GPR[A] = address of B

GPR[B] = 4 \[\text{index to B}[-1]\]

```stxvw4x Xs,Ra,Rb```

**Figure 126. Process to store misaligned quadword to little-endian storage Store VSX Vector Word*4 Indexed**

### 7.5.3 Storage Access Exceptions

Storage accesses cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (Store only), or if the program attempts to access storage that is unavailable.

The address used for VSX storage accesses must be word-aligned to guarantee the access can be performed in hardware rather than result in an Alignment interrupt.
7.6 VSX Instruction Set

7.6.1 VSX Instruction Set Summary

7.6.1.1 VSX Storage Access Instructions

There are two basic forms of scalar load and scalar store instructions, word and doubleword. VSX Scalar Load instructions place a copy of the contents of the addressed word or doubleword in storage into the left-most word or doubleword element of the target VSR. The contents of the right-most element(s) of the target VSR are undefined. VSX Scalar Store instructions place a copy of the contents of the left-most word or doubleword element in the source VSR into the addressed word or doubleword in storage.

There are two basic forms of vector load and vector store instructions, a vector of 4 word elements and a vector of two doublewords. Both forms access a quadword in storage.

There is one basic form of vector load and splat instruction, doubleword. VSX Vector Load and Splat instruction places a copy of the contents of the addressed doubleword in storage into both doubleword elements of the target VSR.

7.6.2 VSX Instruction Description Conventions

7.6.2.1 VSX Instruction RTL Operators

x.bit[y]
    Return the contents of bit y of x.

x.bit[y:z]
    Return the contents of bits y:z of x.

x.word[y]
    Return the contents of word element y of x.

x.word[y:z]
    Return the contents of word elements y:z of x.

x.dword[y]
    Return the contents of doubleword element y of x.

x.dword[y:z]
    Return the contents of doubleword elements y:z of x.

x = y
    The value of y is placed into x.

x |= y
    The value of y is ORed with the value x and placed into x.

~x
    Return the one’s complement of x.

!x
    Return 1 if the contents of x are equal to 0, otherwise return 0.

x | | y
    Return the value of x concatenated with the value of y. For example, 0b010 || 0b111 is the same as 0b010111.

x ^ y
    Return the value of x exclusive ORed with the value of y.

x ? y : z
    If the value of x is true, return the value of y, otherwise return the value z.

x+y
    x and y are integer values.
    Return the sum of x and y.

x–y
    x and y are integer values.
    Return the difference of x and y.
7.6.2.2 VSX Instruction RTL Function Calls

AddDP(x, y)

x and y are double-precision floating-point values.

If x or y is an SNaN, vxsnan_flag is set to 1.

If x is an Infinity and y is an Infinity of the opposite sign, vxisi_flag is set to 1.

If x is a QNaN, return x.
Otherwise, if x is an SNaN, return x represented as a QNaN.
Otherwise, if y is a QNaN, return y.
Otherwise, if y is an SNaN, return y represented as a QNaN.
Otherwise, if x and y are infinities of opposite sign, return the standard QNaN.
Otherwise, return the normalized sum of x and y, having unbounded range and precision.

AddSP(x, y)

x and y are single-precision floating-point values.

If x or y is an SNaN, vxsnan_flag is set to 1.

If x is an Infinity and y is an Infinity of the opposite sign, vxisi_flag is set to 1.

If x is a QNaN, return x.
Otherwise, if x is an SNaN, return x represented as a QNaN.
Otherwise, if y is a QNaN, return y.
Otherwise, if y is an SNaN, return y represented as a QNaN.
Otherwise, if x and y are infinities of opposite sign, return the standard QNaN.
Otherwise, return the normalized sum of x added to y, having unbounded range and precision.

ClassDP(x, y)

Return a 5-bit characterization of the double-precision floating-point number x.

0b10001 = Quiet NaN
0b01001 = -Infinity
0b01000 = -Normalized Number
0b11000 = -Denormalized Number
0b10010 = -Zero
0b00010 = +Zero
0b10100 = +Denormalized Number
0b00100 = +Normalized Number
0b00101 = +Infinity

ClassSP(x, y)

Return a 5-bit characterization of the single-precision floating-point number x.

0b10001 = Quiet NaN
0b01001 = -Infinity
0b01000 = -Normalized Number
0b11000 = -Denormalized Number
0b10010 = -Zero
0b00010 = +Zero
0b10100 = +Denormalized Number
0b00100 = +Normalized Number
0b00101 = +Infinity
CompareEQDP(x, y)
  x and y are double-precision floating-point values.

  If x or y is a NaN, return 0.
  Otherwise, if x is equal to y, return 1.
  Otherwise, return 0.

CompareEQSP(x, y)
  x and y are single-precision floating-point values.

  If x or y is a NaN, return 0.
  Otherwise, if x is equal to y, return 1.
  Otherwise, return 0.

CompareGTDP(x, y)
  x and y are double-precision floating-point values.

  If x or y is a NaN, return 0.
  Otherwise, if x is greater than y, return 1.
  Otherwise, return 0.

CompareGTSP(x, y)
  x and y are single-precision floating-point values.

  If x or y is a NaN, return 0.
  Otherwise, if x is greater than y, return 1.
  Otherwise, return 0.

CompareLTDP(x, y)
  x and y are double-precision floating-point values.

  If x or y is a NaN, return 0.
  Otherwise, if x is less than y, return 1.
  Otherwise, return 0.

CompareLTSP(x, y)
  x and y are single-precision floating-point values.

  If x or y is a NaN, return 0.
  Otherwise, if x is less than y, return 1.
  Otherwise, return 0.

ConvertDPtoSD(x)
  x is a double-precision integer value.

  If x is a NaN,
    return 0x8000_0000_0000_0000, vxcvi_flag is set to 1, and vxsnan_flag is set to 1 if x is an SNaN.
  Otherwise, do the following.
    If x is greater than 2^{63}-1,
      return 0x7FFF_FFFF_FFFF_FFFF and vxcvi_flag is set to 1.
    Otherwise, if x is less than -2^{63},
      return 0x8000_0000_0000_0000 and vxcvi_flag is set to 1.
  Otherwise, return the value x in 64-bit signed integer format.
ConvertDPtoSP(x)

x is a double-precision floating-point value.

If x is an SNaN, \texttt{vxsnan\_flag} is set to 1.

If x is a SNaN, returns x, converted to a QNaN, in single-precision floating-point format.

Otherwise, if x is a QNaN, an Infinity, or a Zero, returns x in single-precision floating-point format.

Otherwise, returns x, rounded to single-precision using the rounding mode specified in RN, in single-precision floating-point format.

\texttt{ox\_flag} is set to 1 if rounding x resulted in an Overflow exception.
\texttt{ux\_flag} is set to 1 if rounding x resulted in an Underflow exception.
\texttt{xx\_flag} is set to 1 if rounding x returns an inexact result.
\texttt{inc\_flag} is set to 1 if the significand of the result was incremented during rounding.

ConvertDPtoSP\_NS(x)

x is a single-precision floating-point value represented in double-precision format.

Returns x in single-precision format.

\begin{verbatim}
sign ← x.bit[0]
exponent ← x.bit[1:11]
fraction ← 0b1 || x.bit[12:63] // implicit bit set to 1 (for now)

if (exponent == 0) & (fraction.bit[1:52] != 0) then do // DP Denormal operand
    exponent ← 0b000_0000_0001 // exponent override to DP Emin = 1
    fraction.bit[0] ← 0b0 // implicit bit override to 0
end

if (exponent < 897) && (fraction != 0) then do // SP tiny operand
    fraction ← fraction >>ui (897 - exponent) // denormalize until exponent = SP Emin
    exponent ← 0b011_1000_0000 // exponent override to SP Emin-1 = 896
end

return(sign || exponent.bit[0] || exponent.bit[4:10] || fraction.bit[1:23])
\end{verbatim}

Programming Note

If x is not representable in single-precision, some exponent and/or significand bits will be discarded, likely producing undesirable results. The low-order 29 bits of the significand of x are discarded, more if the unbiased exponent of x is less than -126 (i.e., denormal). Finite values of x having an unbiased exponent less than -155 will return a result of Zero. Finite values of x having an unbiased exponent greater than +127 will result in discarding significant bits of the exponent. SNaN inputs having no significant bits in the upper 23 bits of the significand will return Infinity as the result. No status is set for any of these cases.
ConvertDPtoSW(x)
   x is a double-precision integer value.

   If x is a NaN,
   return 0x8000_0000,
   vxcvi_flag is set to 1, and
   vxsnan_flag is set to 1 if x is an SNaN

   Otherwise, do the following.
   If x is greater than $2^{31}-1$,
   return 0x7FFF_FFFF and
   vxcvi_flag is set to 1.

   Otherwise, if x is less than $-2^{31}$,
   return 0x8000_0000 and
   vxcvi_flag is set to 1.

   Otherwise, return the value x in 32-bit signed integer format.

ConvertDPtoUD(x)
   x is a double-precision integer value.

   If x is a NaN,
   return 0x0000_0000_0000_0000,
   vxcvi_flag is set to 1, and
   vxsnan_flag is set to 1 if x is an SNaN

   Otherwise, do the following.
   If x is greater than $2^{64}-1$,
   return 0xFFFF_FFFF_FFFF_FFFF and
   vxcvi_flag is set to 1.

   Otherwise, if x is less than 0,
   return 0x0000_0000_0000_0000 and
   vxcvi_flag is set to 1.

   Otherwise, return the value x in 64-bit unsigned integer format.

ConvertDPtoUW(x)
   x is a double-precision integer value.

   If x is a NaN,
   return 0x0000_0000,
   vxcvi_flag is set to 1, and
   vxsnan_flag is set to 1 if x is an SNaN

   Otherwise, do the following.
   If x is greater than $2^{32}-1$,
   return 0xFFFF_FFFF and
   vxcvi_flag is set to 1.

   Otherwise, if x is less than 0,
   return 0x0000_0000 and
   vxcvi_flag is set to 1.

   Otherwise, return the value x in 32-bit unsigned integer format.

ConvertFPtoDP(x)
   Return the floating-point value x in DP format.
ConvertFPtoSP(x)
Return the floating-point value x in single-precision format.

ConvertSDtoFP(x)
x is a 64-bit signed integer value.
Return the value x converted to floating-point format having unbounded significand precision.

ConvertSPtoDP_NS(x)
x is a single-precision floating-point value.
Returns x in double-precision format.

\[
\begin{align*}
\text{sign} & \leftarrow x.\text{bit}[0] \\
\text{exponent} & \leftarrow (x.\text{bit}[1] \lor \neg x.\text{bit}[1] \lor \neg x.\text{bit}[1] \lor \neg x.\text{bit}[1] \lor x.\text{bit}[2:8]) \\

      // normalize operand
      fraction \leftarrow fraction << 1
      exponent \leftarrow exponent + 1
   end
end

return(sign \lor exponent \lor fraction.bit[1:52])
ConvertSP64toSP(x)

x is a single-precision floating-point value in double-precision format.

Returns the value x in single-precision format. x must be representable in single-precision, or else result returned is undefined. x may require denormalization. No rounding is performed. If x is a SNaN, it is converted to a single-precision SNaN having the same payload as x.

\[
\begin{align*}
\text{sign} & \leftarrow x.\text{bit}[0] \\

& \quad \text{end}
\end{align*}
\]

ConvertSPtoDP(x)

x is a single-precision floating-point value.

If x is an SNaN, vxsnan_flag is set to 1.

If x is an SNaN, return x represented as a QNaN in double-precision floating-point format. Otherwise, if x is a QNaN, return x in double-precision floating-point format. Otherwise, the value x in double-precision floating-point format.

ConvertSPtoSD(x)

x is a single-precision integer value.

If x is a NaN,

\[
\text{return } 0x8000_0000_0000_0000 \quad \text{and} \\
\text{vxvcvi_flag is set to 1, and} \\
\text{vxsnan_flag is set to 1 if x is an SNaN}
\]

Otherwise, do the following.
If \( x \) is greater than \( 2^{63}-1 \),
\[
\text{return } 0x7FFF_FFFF_FFFF_FFFF \text{ and } \text{vxcvi\_flag is set to 1.}
\]

Otherwise, if \( x \) is less than \(-2^{63} \),
\[
\text{return } 0x8000_0000_0000_0000 \text{ and } \text{vxcvi\_flag is set to 1.}
\]

Otherwise, return the value \( x \) in 64-bit signed integer format.

\textbf{ConvertSPtoSP64}(x)

\( x \) is a floating-point value in single-precision format.

Returns the value \( x \) in double-precision format. If \( x \) is a SNaN, it is converted to a double-precision SNaN having the same payload as \( x \).

\[
\begin{align*}
\text{sign} & \leftarrow x.\text{bit}[0] \\
\text{exp} & \leftarrow x.\text{bit}[1:8] - 127 \\
\text{frac} & \leftarrow x.\text{bit}[9:31]
\end{align*}
\]

\[
\begin{align*}
\text{if (exp = –127) \&\&(frac != 0) then do} & // \text{Normalize the Denormal value} \\
\text{msb} & \leftarrow frac.\text{bit}[0] \\
\text{frac} & \leftarrow frac \ll 1 \\
\text{do while (msb = 0)} & \\
\text{msb} & \leftarrow frac.\text{bit}[0] \\
\text{frac} & \leftarrow frac \ll 1 \\
\text{exp} & \leftarrow exp - 1 \\
\text{end}
\end{align*}
\]

\[
\begin{align*}
\text{else if (exp = –127) \&\&(frac = 0) then exp} & \leftarrow –1023 // \text{Zero value} \\
\text{else if (exp = +128) \&\& then exp} & \leftarrow +1024 // \text{Infinity, NaN}
\end{align*}
\]

\[
\begin{align*}
\text{result.}\text{bit}[0] & \leftarrow \text{sign} \\
\text{result.}\text{bit}[1:11] & \leftarrow \text{exp} + 1023 \\
\text{result.}\text{bit}[12:34] & \leftarrow \text{frac} \\
\text{result.}\text{bit}[35:63] & \leftarrow 0 \\
\text{return(result)}
\end{align*}
\]

\textbf{ConvertSPtoSW}(x)

\( x \) is a single-precision integer value.

If \( x \) is a NaN,
\[
\text{return } 0x8000_0000, \text{vxcvi\_flag is set to 1, and} \\
\text{vxsnan\_flag is set to 1 if } x \text{ is an SNaN}
\]

Otherwise, do the following.

If \( x \) is greater than \( 2^{31}-1 \),
\[
\text{return } 0x7FFF_FFFF \text{ and } \text{vxcvi\_flag is set to 1.}
\]

Otherwise, if \( x \) is less than \(-2^{31} \),
\[
\text{return } 0x8000_0000 \text{ and } \text{vxcvi\_flag is set to 1.}
\]

Otherwise, return the value \( x \) in 32-bit signed integer format.

\textbf{ConvertSPtoUD}(x)

\( x \) is a single-precision integer value.

If \( x \) is a NaN,
\[
\text{return } 0x0000_0000_0000_0000, \\
\text{vxcvi\_flag is set to 1.}
\]

Otherwise, do the following.

If \( x \) is greater than \( 2^{31}-1 \),
\[
\text{return } 0x7FFF_FFFF \text{ and } \text{vxcvi\_flag is set to 1.}
\]

Otherwise, if \( x \) is less than \(-2^{31} \),
\[
\text{return } 0x8000_0000 \text{ and } \text{vxcvi\_flag is set to 1.}
\]

Otherwise, return the value \( x \) in 32-bit signed integer format.
vxci_flag is set to 1, and
vxsnan_flag is set to 1 if x is an SNaN

Otherwise, do the following.
If x is greater than $2^{54}-1$,
    return 0xFFFF_FFFF_FFFF_FFFF and
    vxci_flag is set to 1.

Otherwise, if x is less than 0,
    return 0x0000_0000_0000_0000 and
    vxci_flag is set to 1.

Otherwise, return the value x in 64-bit unsigned integer format.

ConvertSPtoUW(x)
  x is a single-precision integer value.

  If x is a NaN,
    return 0x0000_0000,
    vxci_flag is set to 1, and
    vxsnan_flag is set to 1 if x is an SNaN

  Otherwise, do the following.
    If x is greater than $2^{32}-1$,
        return 0xFFFF_FFFF and
        vxci_flag is set to 1.

    Otherwise, if x is less than 0,
        return 0x0000_0000 and
        vxci_flag is set to 1.

  Otherwise, return the value x in 32-bit unsigned integer format.

ConvertSWtoFP(x)
  x is a 32-bit signed integer value.

  Return the value x converted to floating-point format having unbounded significand precision.

ConvertUdtoFP(x)
  x is a 64-bit unsigned integer value.

  Return the value x converted to floating-point format having unbounded significand precision.

ConvertUWtoFP(x)
  x is a 32-bit unsigned integer value.

  Return the value x converted to floating-point format having unbounded significand precision.
**DivideDP(x,y)**

x and y are double-precision floating-point values.

- If x or y is an SNaN, `vxsnan_flag` is set to 1.
- If x is a Zero and y is a Zero, `vxzdz_flag` is set to 1.
- If x is a finite, nonzero value and y is a Zero, `zx_flag` is set to 1.
- If x is an Infinity and y is an Infinity, `vxidi_flag` is set to 1.
- If x is a QNaN, return x.
- Otherwise, if x is an SNaN, return x represented as a QNaN.
- Otherwise, if y is a QNaN, return y.
- Otherwise, if y is an SNaN, return y represented as a QNaN.
- Otherwise, if x is a Zero and y is a Zero, return the standard QNaN.
- Otherwise, if x is a finite, nonzero value and y is a Zero with the same sign as x, return +Infinity.
- Otherwise, if x is a finite, nonzero value and y is a Zero with the opposite sign as x, return -Infinity.
- Otherwise, if x is an Infinity and y is an Infinity, return the standard QNaN.
- Otherwise, return the normalized quotient of x divided by y, having unbounded range and precision.

**DivideSP(x,y)**

x and y are single-precision floating-point values.

- If x or y is an SNaN, `vxsnan_flag` is set to 1.
- If x is a Zero and y is a Zero, `vxzdz_flag` is set to 1.
- If x is a finite, nonzero value and y is a Zero, `zx_flag` is set to 1.
- If x is an Infinity and y is an Infinity, `vxidi_flag` is set to 1.
- If x is a QNaN, return x.
- Otherwise, if x is an SNaN, return x represented as a QNaN.
- Otherwise, if y is a QNaN, return y.
- Otherwise, if y is an SNaN, return y represented as a QNaN.
- Otherwise, if x is a Zero and y is a Zero, return the standard QNaN.
- Otherwise, if x is a finite, nonzero value and y is a Zero with the same sign as x, return +Infinity.
- Otherwise, if x is a finite, nonzero value and y is a Zero with the opposite sign as x, return -Infinity.
- Otherwise, if x is an Infinity and y is an Infinity, return the standard QNaN.
- Otherwise, return the normalized quotient of x divided by y, having unbounded range and precision.

**DenormDP(x)**

x is a floating-point value having unbounded range and precision.

Return the value x with its significand shifted right by a number of bits equal to the difference of the -1022 and the unbiased exponent of x, and its unbiased exponent set to -1022.

**DenormSP(x)**

x is a floating-point value having unbounded range and precision.

Return the value x with its significand shifted right by a number of bits equal to the difference of the -126 and the unbiased exponent of x, and its unbiased exponent set to -126.

**IsInf(x)**

Return 1 if x is an Infinity, otherwise return 0.

**isNaN(x)**

Return 1 if x is either an SNaN or a QNaN, otherwise return 0.
IsNeg(x)
Return 1 if x is a negative, nonzero value, otherwise return 0.

IsSNaN(x)
Return 1 if x is an SNaN, otherwise return 0.

IsZero(x)
Return 1 if x is a Zero, otherwise return 0.

MaximumDP(x,y)
x and y are double-precision floating-point values.

If x or y is an SNaN, vxsnan_flag is set to 1.
If x is a QNaN and y is not a NaN, return y.
Otherwise, if x is a QNaN, return x.
Otherwise, if x is an SNaN, return x represented as a QNaN.
Otherwise, if y is a QNaN, return x.
Otherwise, if y is an SNaN, return y represented as a QNaN.
Otherwise, return the greater of x and y, where +0 is considered greater than –0.

MaximumSP(x,y)
x and y are single-precision floating-point values.

If x or y is an SNaN, vxsnan_flag is set to 1.
If x is a QNaN and y is not a NaN, return y.
Otherwise, if x is a QNaN, return x.
Otherwise, if x is an SNaN, return x represented as a QNaN.
Otherwise, if y is a QNaN, return x.
Otherwise, if y is an SNaN, return y represented as a QNaN.
Otherwise, return the greater of x and y, where +0 is considered greater than –0.

MEM(x,y)
Contents of a sequence of y bytes of storage. The sequence depends on the endianness of the storage access as follows.
– For big-endian storage accesses, the sequence starts with the byte at address x and ends with the byte at address x+y-1.
– For little-endian storage accesses, the sequence starts with the byte at address x+y-1 and ends with the byte at address x.

MinimumDP(x,y)
x and y are double-precision floating-point values.

If x or y is an SNaN, vxsnan_flag is set to 1.
If x is a QNaN and y is not a NaN, return y.
Otherwise, if x is a QNaN, return x.
Otherwise, if x is an SNaN, return x represented as a QNaN.
Otherwise, if y is a QNaN, return x.
Otherwise, if y is an SNaN, return y represented as a QNaN.
Otherwise, return the lesser of x and y, where –0 is considered less than +0.
MinimumSP(x,y)
   x and y are single-precision floating-point values.

   If x or y is an SNaN, vxsnan_flag is set to 1.

   If x is a QNaN and y is not a NaN, return y.
   Otherwise, if x is a QNaN, return x.
   Otherwise, if x is an SNaN, return x represented as a QNaN.
   Otherwise, if y is a QNaN, return x.
   Otherwise, if y is an SNaN, return y represented as a QNaN.
   Otherwise, return the lesser of x and y, where –0 is considered less than +0.

MultiplyAddDP(x,y,z)
   x, y and z are double-precision floating-point values.

   If x, y or z is an SNaN, vxsnan_flag is set to 1.

   If x is a Zero and y, is an Infinity or x is an Infinity and y is an Zero, vximz_flag is set to 1.

   If the product of x and y is an Infinity and z is an Infinity of the opposite sign, vxisi_flag is set to 1.

   If x is a QNaN, return x.
   Otherwise, if x is an SNaN, return x represented as a QNaN.
   Otherwise, if z is a QNaN, return z.
   Otherwise, if z is an SNaN, return z represented as a QNaN.
   Otherwise, if y is a QNaN, return y.
   Otherwise, if y is an SNaN, return y represented as a QNaN.
   Otherwise, if y is a QNaN, return the standard QNaN.
   Otherwise, if the product of x and y is an Infinity, and z is an Infinity of the opposite sign, return the standard QNaN.
   Otherwise, return the normalized sum of z and the product of x and y, having unbounded range and precision.

MultiplyAddSP(x,y,z)
   x, y and z are single-precision floating-point values.

   If x, y or z is an SNaN, vxsnan_flag is set to 1.

   If x is a Zero and y is an Infinity, or x is an Infinity and y is an Zero, vximz_flag is set to 1.

   If the product of x and y is an Infinity and z is an Infinity of the opposite sign, vxisi_flag is set to 1.

   If x is a QNaN, return x.
   Otherwise, if x is an SNaN, return x represented as a QNaN.
   Otherwise, if z is a QNaN, return z.
   Otherwise, if z is an SNaN, return z represented as a QNaN.
   Otherwise, if y is a QNaN, return y.
   Otherwise, if y is an SNaN, return y represented as a QNaN.
   Otherwise, if x is a Zero and y is an Infinity or x is an Infinity and y is an Zero, return the standard QNaN.
   Otherwise, if the product of x and y is an Infinity, and z is an Infinity of the opposite sign, return the standard QNaN.
   Otherwise, return the normalized sum of z and the product of x and y, having unbounded range and precision.
MultiplyDP(x, y)
  x and y are double-precision floating-point values.

  If x or y is an SNaN, vxsnan_flag is set to 1.

  If x is a Zero and y is an Infinity, or x is an Infinity and y is an Zero, vximz_flag is set to 1.

  If x is a QNaN, return x.
  Otherwise, if x is an SNaN, return x represented as a QNaN.
  Otherwise, if y is a QNaN, return y.
  Otherwise, if y is an SNaN, return y represented as a QNaN.
  Otherwise, if x is a Zero and y is an Infinity or x is an Infinity and y is an Zero, return the standard QNaN.
  Otherwise, return the normalized product of x and y, having unbounded range and precision.

MultiplySP(x, y)
  x and y are single-precision floating-point values.

  If x or y is an SNaN, vxsnan_flag is set to 1.

  If x is a Zero and y is an Infinity, or x is an Infinity and y is an Zero, vximz_flag is set to 1.

  If x is a QNaN, return x.
  Otherwise, if x is an SNaN, return x represented as a QNaN.
  Otherwise, if y is a QNaN, return y.
  Otherwise, if y is an SNaN, return y represented as a QNaN.
  Otherwise, if x is a Zero and y is an Infinity or x is an Infinity and y is an Zero, return the standard QNaN.
  Otherwise, return the normalized product of x and y, having unbounded range and precision.

NegateDP(x)
  If the double-precision floating-point value x is a NaN, return x.
  Otherwise, return the double-precision floating-point value x with its sign bit complemented.

NegateSP(x)
  If the single-precision floating-point value x is a NaN, return x.
  Otherwise, return the single-precision floating-point value x with its sign bit complemented.

ReciprocalEstimateDP(x)
  x is a double-precision floating-point value.

  If x is an SNaN, vxsnan_flag is set to 1.

  If x is a Zero, zx_flag is set to 1.

  If x is a QNaN, return x.
  Otherwise, if x is an SNaN, return x represented as a QNaN.
  Otherwise, if x is a Zero, return an Infinity with the sign of x.
  Otherwise, if x is an Infinity, return a Zero with the sign of x.
  Otherwise, return an estimate of the reciprocal of x having unbounded exponent range.
ReciprocalEstimateSP(x)
   x is a single-precision floating-point value.
   
   If x is an SNaN, \texttt{vxsnan\_flag} is set to 1.
   
   If x is a Zero, \texttt{zx\_flag} is set to 1.
   
   If x is a QNaN, return x.
   Otherwise, if x is an SNaN, return x represented as a QNaN.
   Otherwise, if x is a Zero, return an Infinity with the sign of x.
   Otherwise, if x is an Infinity, return a Zero with the sign of x.
   Otherwise, return an estimate of the reciprocal of x having unbounded exponent range.

ReciprocalSquareRootEstimateDP(x)
   x is a double-precision floating-point value.
   
   If x is an SNaN, \texttt{vxsnan\_flag} is set to 1.
   
   If x is a Zero, \texttt{zx\_flag} is set to 1.
   
   If x is a negative, nonzero number, \texttt{vxsqrt\_flag} is set to 1.
   
   If x is a QNaN, return x.
   Otherwise, if x is an SNaN, return x represented as a QNaN.
   Otherwise, if x is a negative, nonzero value, return the default QNaN.
   Otherwise, return an estimate of the reciprocal of the square root of x having unbounded exponent range.

ReciprocalSquareRootEstimateSP(x)
   x is a single-precision floating-point value.
   
   If x is an SNaN, \texttt{vxsnan\_flag} is set to 1.
   
   If x is a Zero, \texttt{zx\_flag} is set to 1.
   
   If x is a negative, nonzero number, \texttt{vxsqrt\_flag} is set to 1.
   
   If x is a QNaN, return x.
   Otherwise, if x is an SNaN, return x represented as a QNaN.
   Otherwise, if x is a negative, nonzero value, return the default QNaN.
   Otherwise, return an estimate of the reciprocal of the square root of x having unbounded exponent range.

reset\_xflags()
   \texttt{vxsnan\_flag} is set to 0.
   \texttt{vximz\_flag} is set to 0.
   \texttt{vxidi\_flag} is set to 0.
   \texttt{vxisi\_flag} is set to 0.
   \texttt{vxzdz\_flag} is set to 0.
   \texttt{vxsqrt\_flag} is set to 0.
   \texttt{vxcvi\_flag} is set to 0.
   \texttt{vxvc\_flag} is set to 0.
   \texttt{ox\_flag} is set to 0.
   \texttt{ux\_flag} is set to 0.
   \texttt{xx\_flag} is set to 0.
   \texttt{zx\_flag} is set to 0.
RoundToDP(x, y)

x is a 2-bit unsigned integer specifying one of four rounding modes.

- 0b00: Round to Nearest Even
- 0b01: Round towards Zero
- 0b10: Round towards +Infinity
- 0b11: Round towards - Infinity

y is a normalized floating-point value having unbounded range and precision.

Return the value y rounded to double-precision under control of the rounding mode specified by x.

```plaintext

RoundToDPCeil(x)
   x is a floating-point value having unbounded range and precision.
   
   If x is a QNaN, return x.
   
   Otherwise, if x is an Infinity, return x.
   
   Otherwise, do the following.
   Return the smallest floating-point number having unbounded exponent range but double-precision
   significand precision that is greater or equal in value to x.
   
   If the magnitude of the value returned is greater than x, inc_flag is set to 1.
   
   If the value returned is not equal to x, xx_flag is set to 1.
   
RoundToDPFloor(x)
   x is a floating-point value having unbounded range and precision.
   
   If x is a QNaN, return x.
   
   Otherwise, if x is an Infinity, return x.
   
   Otherwise, do the following.
   Return the largest floating-point number having unbounded exponent range but double-precision
   significand precision that is lesser or equal in value to x.
   
   If the magnitude of the value returned is greater than x, inc_flag is set to 1.
   
   If the value returned is not equal to x, xx_flag is set to 1.
   
RoundToDPIntegerCeil(x)
   x is a double-precision floating-point value.
   
   If x is an SNaN, vxsnan_flag is set to 1.
   
   If x is a QNaN, return x.
   
   Otherwise, if x is an SNaN, return x represented as a QNaN.
   
   Otherwise, if x is an infinity, return x.
   
   Otherwise, do the following.
   Return the smallest double-precision floating-point integer value that is greater or equal in value to x.
   
   If the magnitude of the value returned is greater than x, inc_flag is set to 1.
   
   If the value returned is not equal to x, xx_flag is set to 1.
RoundToDPIntegerFloor(x)

x is a double-precision floating-point value.

If x is an SNaN, vxsnan_flag is set to 1.
If x is a QNaN, return x.
Otherwise, if x is an SNaN, return x represented as a QNaN.
Otherwise, if x is an infinity, return x.
Otherwise, do the following.
Return the largest double-precision floating-point integer value that is lesser or equal in value to x
If the magnitude of the value returned is greater than x, inc_flag is set to 1.
If the value returned is not equal to x, xx_flag is set to 1.

RoundToDPIntegerNearAway(x)

x is a double-precision floating-point value.

If x is an SNaN, vxsnan_flag is set to 1.
If x is a QNaN, return x.
Otherwise, if x is an SNaN, return x represented as a QNaN.
Otherwise, if x is an infinity, return x.
Otherwise, do the following.
Return the largest double-precision floating-point integer value that is lesser or equal in value to x+0.5 if x>0, or the smallest double-precision floating-point integer that is greater or equal in value to x-0.5 if x<0.
If the magnitude of the value returned is greater than x, inc_flag is set to 1.
If the value returned is not equal to x, xx_flag is set to 1.

RoundToDPIntegerNearEven(x)

x is a double-precision floating-point value.

If x is an SNaN, vxsnan_flag is set to 1.
If x is a QNaN, return x.
Otherwise, if x is an SNaN, return x represented as a QNaN.
Otherwise, if x is an infinity, return x.
Otherwise, do the following.
Return the double-precision floating-point integer value that is nearest in value to x (in case of a tie, the double-precision floating-point integer value with the least-significant bit equal to 0 is used).
If the magnitude of the value returned is greater than x, inc_flag is set to 1.
If the value returned is not equal to x, xx_flag is set to 1.
RoundToDPIntegerTrunc(x)

x is a double-precision floating-point value.

If x is an SNaN, \(vxsnan\_flag\) is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is an infinity, return x.

Otherwise, do the following.
Return the largest double-precision floating-point integer value that is lesser or equal in value to x if x>0, or the smallest double-precision floating-point integer value that is greater or equal in value to x if x<0.

If the magnitude of the value returned is greater than x, \(inc\_flag\) is set to 1.

If the value returned is not equal to x, \(xx\_flag\) is set to 1.

RoundToDPNearEven(x)

x is a floating-point value having unbounded range and precision.

If x is a QNaN, return x.

Otherwise, if x is an Infinity, return x.

Otherwise, do the following.
Return the floating-point number having unbounded exponent range but double-precision significand precision that is nearest in value to x (in case of a tie, the floating-point number having unbounded exponent range but double-precision significand precision with the least-significant bit equal to 0 is used).

If the magnitude of the value returned is greater than x, \(inc\_flag\) is set to 1.

If the value returned is not equal to x, \(xx\_flag\) is set to 1.

RoundToDPTrunc(x)

x is a floating-point value having unbounded range and precision.

If x is a QNaN, return x.

Otherwise, if x is an Infinity, return x.

Otherwise, do the following.
Return the largest floating-point number having unbounded exponent range but double-precision significand precision that is lesser or equal in value to x if x>0, or the smallest floating-point number having unbounded exponent range but double-precision significand precision that is greater or equal in value to x if x<0.

If the magnitude of the value returned is greater than x, \(inc\_flag\) is set to 1.

If the value returned is not equal to x, \(xx\_flag\) is set to 1.
RoundToSP(x,y)

x is a 2-bit unsigned integer specifying one of four rounding modes.

- 0b00: Round to Nearest Even
- 0b01: Round towards Zero
- 0b10: Round towards +Infinity
- 0b11: Round towards -Infinity

y is a normalized floating-point value having unbounded range and precision.

Return the value y rounded to single-precision under control of the rounding mode specified by x.

```plaintext
if IsQNaN(y) then return ConvertFPtoSP(y)
if IsInf(y) then return ConvertFPtoSP(y)
if IsZero(y) then return ConvertFPtoSP(y)
if y<Nmin then do
  if UE=0 then do
    if x=0b00 then r ← RoundToSPNearEven( DenormSP(y) )
    if x=0b01 then r ← RoundToSPTrunc( DenormSP(y) )
    if x=0b10 then r ← RoundToSPCeil( DenormSP(y) )
    if x=0b11 then r ← RoundToSPFloor( DenormSP(y) )
    ux_flag ← xx_flag
    return(ConvertFPtoSP(r))
  end
  else do
    y ← Scalb(y,+192)
    ux_flag ← 1
  end
end
if x=0b00 then r ← RoundToSPNearEven(y)
if x=0b01 then r ← RoundToSPTrunc(y)
if x=0b10 then r ← RoundToSPCeil(y)
if x=0b11 then r ← RoundToSPFloor(y))
if r>Nmax then do
  if OE=0 then do
    if x=0b00 then r ← sign ? -Inf : +Inf
    if x=0b01 then r ← sign ? -Nmax : +Nmax
    if x=0b10 then r ← sign ? -Nmax : +Inf
    if x=0b11 then r ← sign ? -Inf : +Nmax
    ox_flag ← 0b1
    xx_flag ← 0b1
    inc_flag ← 0bU
    return(ConvertFPtoSP(r))
  end
  else do
    r ← Scalb(r,-192)
    ox_flag ← 1
  end
end
return(ConvertFPtoSP(r))
```
RoundToSPCeil(x)
x is a floating-point value having unbounded range and precision.

If x is a QNaN, return x.

Otherwise, if x is an Infinity, return x.

Otherwise, do the following.
Return the smallest floating-point number having unbounded exponent range but single-precision significand precision that is greater or equal in value to x.

If the magnitude of the value returned is greater than x, inc_flag is set to 1.

If the value returned is not equal to x, xx_flag is set to 1.

RoundToSPFloor(x)
x is a floating-point value having unbounded range and precision.

If x is a QNaN, return x.

Otherwise, if x is an Infinity, return x.

Otherwise, do the following.
Return the largest floating-point number having unbounded exponent range but single-precision significand precision that is lesser or equal in value to x.

If the magnitude of the value returned is greater than x, inc_flag is set to 1.

If the value returned is not equal to x, xx_flag is set to 1.

RoundToSPIntegerCeil(x)
x is a single-precision floating-point value.

If x is an SNaN, vxsnan_flag is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is an infinity, return x.

Otherwise, do the following.
Return the smallest single-precision floating-point integer value that is greater or equal in value to x.

If the magnitude of the value returned is greater than x, inc_flag is set to 1.

If the value returned is not equal to x, xx_flag is set to 1.
RoundToSPIntegerFloor(x)
   x is a single-precision floating-point value.
   If x is an SNaN, \(v_{x\text{snan}\_\text{flag}}\) is set to 1.
   If x is a QNaN, return x.
   Otherwise, if x is an SNaN, return x represented as a QNaN.
   Otherwise, if x is an infinity, return x.
   Otherwise, do the following.
      Return the largest single-precision floating-point integer value that is lesser or equal in value to x.
      If the magnitude of the value returned is greater than x, \(\text{inc\_flag}\) is set to 1.
      If the value returned is not equal to x, \(xx\_\text{flag}\) is set to 1.

RoundToSPIntegerNearAway(x)
   x is a single-precision floating-point value.
   If x is an SNaN, \(v_{x\text{snan}\_\text{flag}}\) is set to 1.
   If x is a QNaN, return x.
   Otherwise, if x is an SNaN, return x represented as a QNaN.
   Otherwise, if x is an infinity, return x.
   Otherwise, do the following.
      Return x if x is a floating-point integer; otherwise return the largest single-precision floating-point integer value that is lesser or equal in value to x+0.5 if x>0, or the smallest single-precision floating-point integer value that is greater or equal in value to x-0.5 if x<0.
      If the magnitude of the value returned is greater than x, \(\text{inc\_flag}\) is set to 1.
      If the value returned is not equal to x, \(xx\_\text{flag}\) is set to 1.

RoundToSPIntegerNearEven(x)
   x is a single-precision floating-point value.
   If x is an SNaN, \(v_{x\text{snan}\_\text{flag}}\) is set to 1.
   If x is a QNaN, return x.
   Otherwise, if x is an SNaN, return x represented as a QNaN.
   Otherwise, if x is an infinity, return x.
   Otherwise, do the following.
      Return x if x is a floating-point integer; otherwise return the single-precision floating-point integer value that is nearest in value to x (in case of a tie, the single-precision floating-point integer value with the least-significant bit equal to 0 is used).
      If the magnitude of the value returned is greater than x, \(\text{inc\_flag}\) is set to 1.
      If the value returned is not equal to x, \(xx\_\text{flag}\) is set to 1.
RoundToSPIntegerTrunc(x)
   x is a single-precision floating-point value.

   If x is a QNaN, return x.

   Otherwise, if x is an SNaN, return x represented as a QNaN, and vxsnan_flag is set to 1.

   Otherwise, if x is an infinity, return x.

   Otherwise, do the following.
   Return the largest single-precision floating-point integer value that is lesser or equal in value to x if x>0, or the smallest single-precision floating-point integer value that is greater or equal in value to x if x<0.

   If the magnitude of the value returned is greater than x, inc_flag is set to 1.

   If the value returned is not equal to x, xx_flag is set to 1.

RoundToSPNearEven(x)
   x is a floating-point value having unbounded range and precision.

   If x is a QNaN, return x.

   Otherwise, if x is an Infinity, return x.

   Otherwise, do the following.
   Return the floating-point number having unbounded exponent range but single-precision significand precision that is nearest in value to x (in case of a tie, the floating-point number having unbounded exponent range but single-precision significand precision with the least-significant bit equal to 0 is used).

   If the magnitude of the value returned is greater than x, inc_flag is set to 1.

   If the value returned is not equal to x, xx_flag is set to 1.

RoundToSPTTrunc(x)
   x is a floating-point value having unbounded range and precision.

   If x is a QNaN, return x.

   Otherwise, if x is an Infinity, return x.

   Otherwise, do the following.
   Return the largest floating-point number having unbounded exponent range but single-precision significand precision that is lesser or equal in value to x if x>0, or the smallest single-precision floating-point number that is greater or equal in value to x if x<0.

   If the magnitude of the value returned is greater than x, inc_flag is set to 1.

   If the value returned is not equal to x, xx_flag is set to 1.

Scalb(x,y)
   x is a floating-point value having unbounded range and precision.
   y is a signed integer.

   Result of multiplying the floating-point value x by 2^y.

SetFX(x)
   x is one of the exception flags in the FPSCR.

   If the contents of x is 0, FX and x are set to 1.
SquareRootDP(x)
x is a double-precision floating-point value.

If x is an SNaN, vxsnan_flag is set to 1.
If x is a negative, nonzero value, vxsqrt_flag is set to 1.
If x is a QNaN, return x.
Otherwise, if x is an SNaN, return x represented as a QNaN.
Otherwise, if x is a negative, nonzero value, return the default QNaN.
Otherwise, return the normalized square root of x, having unbounded range and precision.

SquareRootSP(x)
x is a single-precision floating-point value.

If x is an SNaN, vxsnan_flag is set to 1.
If x is a negative, nonzero value, vxsqrt_flag is set to 1.
If x is a QNaN, return x.
Otherwise, if x is an SNaN, return x represented as a QNaN.
Otherwise, if x is a negative, nonzero value, return the default QNaN.
Otherwise, return the normalized square root of x, having unbounded range and precision.
7.6.3 VSX Instruction Descriptions

Load VSX Scalar Doubleword Indexed XX1-form

\[
\text{lxsdx XT,RA,RB}
\]

\[
\begin{array}{cccccc}
31 & T & RA & RB & 588 & TX \\
0 & 6 & 11 & 16 & 21 & 31
\end{array}
\]

\[
\begin{align*}
\text{XT} & \leftarrow \text{TX} || T \\
a[0:63] & \leftarrow \begin{cases} 
0 & \text{if RA} = 0 \\
\text{GPR}[RA] & \text{otherwise}
\end{cases} \\
\text{EA}[0:63] & \leftarrow a + \text{GPR}[RB] \\
\text{VSR}[\text{TX}] & \leftarrow \text{MEM(EA,8)} || 0xUUUU_UUUU_UUUU_UUUU
\end{align*}
\]

Let XT be the value TX concatenated with T.

Let EA be the sum of the contents of GPR[RA], or 0 if RA is equal to 0, and the contents of GPR[RB].

The contents of the doubleword in storage at address EA are placed in doubleword element 0 of VSR[XT].

The contents of doubleword element 1 of VSR[XT] are undefined.

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src2 is added[1] to src1, producing a sum having unbounded range and precision.

The sum is normalized[2].

See Table 48, “Actions for xsadddp,” on page 401.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

---

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:
- src1: The double-precision floating-point value in doubleword element 0 of VSR[XA].
- src2: The double-precision floating-point value in doubleword element 0 of VSR[XB].
- dQNaN: Default quiet NaN (0x7FF8_0000_0000_0000).
- NZF: Nonzero finite number.
- Rezd: Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).
- A(x,y): Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
  Note: If x = -y, v is considered to be an exact-zero-difference result (Rezd).
- Q(x): Return a QNaN with the payload of x.
- v: The intermediate result having unbounded significand precision and unbounded exponent range.

</tbody>
</table>

**Explanation:**
- **v** The precise intermediate result defined in the instruction having unbounded range and precision.
- **Den(x)** The value x is denormalized. The significand is shifted left by the amount of the difference between Emin for the target precision (that is, -1022 for double-precision, -126 for single-precision) and the unbiased exponent of x. The unbiased exponent of the denormalized value is Emin. The significand of the denormalized value has unbounded significand precision.
- **Rezd** Exact-zero-difference result. Applies only to add operations involving source operands having the same magnitude and different signs.
- **Rnd(x)** The significand of x is rounded to the target precision according to the rounding mode specified in FPSCR<sub>RN</sub>. Exponent range of the rounded result is unbounded. See Section 7.3.2.6.
- **Nmax** Largest (in magnitude) representable normalized number in the target precision format.
- **Nmin** Smallest (in magnitude) representable normalized number in the target precision format.
- **ulp** Least significant bit in the target precision format’s significand (Unit in the Last Position).
- **RTN** Round To Nearest, ties to Even.
- **RTZ** Round Toward Zero.
- ** RTP** Round Toward +infinity.
- **RTM** Round Toward −infinity.

**Explanation:**

- The results do not depend on this condition.
- ClassFP(x) Classifies the floating-point value x as defined in Table 2, “Floating-Point Result Flags,” on page 327.
- fx(x) FX is set to 1 if x=0.  x is set to 1.
- β Wrap adjust, where \( \beta = 2^{1536} \) for double-precision and \( \beta = 2^{192} \) for single-precision.
- q The value defined in Table 49, “Floating-Point Intermediate Result Handling,” on page 402, significand rounded to the target precision, unbounded exponent range.
- r The value defined in Table 49, “Floating-Point Intermediate Result Handling,” on page 402, significand rounded to the target precision, bounded exponent range.
- v The precise intermediate result defined in the instruction having unbounded significand precision, unbounded exponent range.
- FI Floating-Point Fraction Inexact status flag, FPSCRFI. This status flag is nonsticky.
- FR Floating-Point Fraction Rounded status flag, FPSCRFR.
- OX Floating-Point Overflow exception status flag, FPSCRFX.
- error() The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode.
- T(x) The value x is placed in element 0 of VSR[XT] in the target precision format.
- UX Floating-Point Underflow exception status flag, FPSCRUX.
- VXSQRT Floating-Point Invalid Operation Exception (SNaN) status flag, FPSCRVXSQRT.
- VXISI Floating-Point Invalid Operation Exception (Infinity – Infinity) status flag, FPSCRVXISI.
- VXZDZ Floating-Point Invalid Operation Exception (Zero ÷ Zero) status flag, FPSCRVXZDZ.
- XX Floating-Point Inexact Exception status flag, FPSCRXX. The flag is a sticky version of FPSCRXX. When FPSCRXX is set to a new value, the new value of FPSCRXX is set to the result of ORing the old value of FPSCRXX with the new value of FPSCRXX.
- ZX Floating-Point Zero Divide Exception status flag, FPSCRZX.

### Explanation:

– The results do not depend on this condition.

ClassFP(x) Classifies the floating-point value x as defined in Table 2, “Floating-Point Result Flags,” on page 327.

fx(x) FX is set to 1 if x=0. x is set to 1.

β Wrap adjust, where $\beta = 2^{1536}$ for double-precision and $\beta = 2^{1022}$ for single-precision.

q The value defined in Table 49, “Floating-Point Intermediate Result Handling,” on page 402, significand rounded to the target precision, unbounded exponent range.

r The value defined in Table 49, “Floating-Point Intermediate Result Handling,” on page 402, significand rounded to the target precision, bounded exponent range.

v The precise intermediate result defined in the instruction having unbounded significand precision, unbounded exponent range.

Fi Floating-Point Fraction Inexact status flag, FPSCR$_{Fx}$. This status flag is nonsticky.

FR Floating-Point Fraction Rounded status flag, FPSCR$_{FR}$.

OX Floating-Point Overflow exception status flag, FPSCR$_{OX}$.

error() The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode.

T(x) The value x is placed in element 0 of VSR[$X$T] in the target precision format.

  FPRF ← ClassSP(result)
  FR ← inc_flag
  FI ← xx_flag
  end
else do
  FR ← 0b0
  FI ← 0b0
end

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src2 is added\(^1\) to src1, producing a sum having unbounded range and precision.

The sum is normalized\(^2\).

See Table 51, “Actions for xsaddsp,” on page 406.

The intermediate result is rounded to single-precision using the rounding mode specified by RN.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

---

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src1 is compared to src2.

Zeros of same or opposite signs compare equal.

Infinities of same signs compare equal.

See Table 52, “Actions for xscmpodp - Part 1: Compare Ordered,” on page 408.

The result of the compare is placed into CR field BF and the FPCC.

If either of the operands is a NaN, either quiet or signaling, CR field BF and the FPCC are set to reflect unordered. If either of the operands is a Signaling NaN, VXSNAN is set, and Invalid Operation is disabled (VE=0), VXVC is set. If neither operand is a Signaling NaN but at least one operand is a Quiet NaN, VXVC is set.

See Table 53, “Actions for xscmpodp - Part 2: Result,” on page 408.

### Explanation:

- **fx(x)**: FX is set to 1 if x=0. x is set to 1.
- **error()**: The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode.
- **Nmin**: The smallest signed integer doubleword value, \(-2^{63} \times 0x8000_0000_0000_0000\).
- **Nmax**: The largest signed integer doubleword value, \(2^{63}-1 \times 0x7FFF_FFFF_FFFF_FFFF\).
- **src**: The double-precision floating-point value in doubleword element 0 of VSR[XB].
- **T(x)**: The signed integer doubleword value x is placed in doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are undefined.

</table>
```

Let XT be the value TX concatenated with T.
Let XB be the value BX concatenated with B.

Let src be the double-precision floating-point value in
doubleword element 0 of VSR[XB].

If src is a NaN, the result is the value 0x8000_0000
and VXCVI is set to 1. If src is an SNaN, VXSNAN is
also set to 1.

Otherwise, src is rounded to a floating-point integer
using the rounding mode Round Toward Zero.

If the rounded value is greater than 2^{31-1}, the result is
0x7FFF_FFFF and VXCVI is set to 1.

Otherwise, if the rounded value is less than -2^{31}, the
result is 0x8000_0000 and VXCVI is set to 1.

Otherwise, the result is the rounded value converted to
32-bit signed-integer format.

If a trap-enabled invalid operation exception occurs,

- VSR[XT] and FPRF are not modified
- FR and FI are set to 0.

Otherwise,

- The result is placed into word element 1 of VSR[XT]. The contents of word elements 0, 2, and 3 of VSR[XT] are undefined.
- FPRF is set to an undefined value.
- FR is set to indicate if the result was incremented when rounded.
- FI is set to indicate the result is inexact.

See Table 57.

### Explanation:

- **fx(x)**: FX is set to 1 if x=0. x is set to 1.
- **error()**: The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode.
- **Nmin**: The smallest signed integer word value, \(-2^{31}(0x8000_0000)\).
- **Nmax**: The largest signed integer word value, \(2^{31}-1 (0x7FFF_FFFF)\).
- **src**: The double-precision floating-point value in doubleword element 0 of VSR[XB].
- **T(x)**: The signed integer word value x is placed in word element 1 of VSR[XT]. The contents of word elements 0, 2, and 3 of VSR[XT] are undefined.

**Table 57. Actions for xscvdpxsxws**
VSX Scalar Truncate Double-Precision Integer and Convert to Unsigned Integer Doubleword Format with Saturate XX2-Form

Let XT be the value TX concatenated with T.
Let XB be the value BX concatenated with B.

Let src be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If src is a NaN, the result is the value 0x0000_0000_0000_0000 and VXCVI is set to 1. If src is an SNaN, VXSNAN is also set to 1.

Otherwise, src is rounded to a floating-point integer using the rounding mode Round Toward Zero.

If the rounded value is greater than 2^{64}-1, the result is 0xFFFF_FFFF_FFFF_FFFF and VXCVI is set to 1.

Otherwise, if the rounded value is less than 0, the result is 0x0000_0000_0000_0000 and VXCVI is set to 1.

Otherwise, the result is the rounded value converted to 64-bit unsigned-integer format.

If a trap-enabled invalid operation exception occurs,

- VSR[XT] and FPRF are not modified
- FR and FI are set to 0.

Otherwise,

- The result is placed into doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are undefined.
- FPRF is set to an undefined value.
- FR is set to indicate if the result was incremented when rounded.

**Explanation:**

- **src1**: The double-precision floating-point value in doubleword element 0 of VSR[XA].
- **src2**: The double-precision floating-point value in doubleword element 0 of VSR[XB].
- **dQNaN**: Default quiet NaN (0x7FF8_0000_0000_0000).
- **NZF**: Nonzero finite number.
- **D(x,y)**: Return the normalized quotient of floating-point value x divided by floating-point value y, having unbounded range and precision.
- **Q(x)**: Return a QNaN with the payload of x.
- **v**: The intermediate result having unbounded significand precision and unbounded exponent range.

### Explanation:

- **src1**: The double-precision floating-point value in doubleword element 0 of VSR[XA].
- **src2**: The double-precision floating-point value in doubleword element 0 of VSR[XB].
- **dQNaN**: Default quiet NaN (0x7FF8_0000_0000_0000).
- **NZF**: Nonzero finite number.
- **D(x,y)**: Return the normalized quotient of floating-point value x divided by floating-point value y, having unbounded range and precision.
- **Q(x)**: Return a QNaN with the payload of x.
- **v**: The intermediate result having unbounded significand precision and unbounded exponent range.
## VSX Scalar Multiply-Add Double-Precision XX3-form

For \textbf{xsmaddadp}, do the following.
- Let \textit{src2} be the double-precision floating-point value in doubleword element 0 of VSR[XB].
- Let \textit{src3} be the double-precision floating-point value in doubleword element 0 of VSR[XT].

\textit{src1} is multiplied\footnote{Floating-point multiplication is based on exponent addition and multiplication of the significands.} by \textit{src3}, producing a product having unbounded range and precision.

See part 1 of Table 62.

\textit{src2} is added\footnote{Floating-point addition is based on exponent comparison and addition of the significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.} to the product, producing a sum having unbounded range and precision.

The sum is normalized\footnote{Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.}.

See part 2 of Table 62.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, "Floating-Point Intermediate Result Handling," on page 402.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are undefined.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 50, “Scalar Floating-Point Final Result,” on page 403.

**Explanation:**

src1 The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2 For xsmadddp, the double-precision floating-point value in doubleword element 0 of VSR[XT].
src3 For xsmadddp, the double-precision floating-point value in doubleword element 0 of VSR[XB].
dQNaN Default quiet NaN ($\text{x07FF_0000_0000_0000}$).
NZF Nonzero finite number.
Rezd Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x) Return the normalized payload of NaN(x).
A(x,y) Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
Note: If $x = -y$, v is considered to be an exact-zero-difference result (Rezd).
M(x,y) Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
p The intermediate product having unbounded range and precision.
v The intermediate result having unbounded range and precision.

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

For \text{xsmaddasp}, do the following.

- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[AX].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[TX].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[BX].

For \text{xsmaddmsp}, do the following.

- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[AX].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[BX].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[TX].

src1 is multiplied\(^1\) by src3, producing a product having unbounded range and precision.

See part 1 of Table 63, “Actions for xsmadd(a|m)sp,” on page 434.

src2 is added\(^2\) to the product, producing a sum having unbounded range and precision.

The sum is normalized\(^3\).

See part 2 of Table 63, “Actions for xsmadd(a|m)sp,” on page 434.

The intermediate result is rounded to single-precision using the rounding mode specified by RN.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are undefined.

FPRF is set to the class and sign of the result as represented in single-precision format. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 50, “Scalar Floating-Point Final Result,” on page 403.

---

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

0 & 6 & T & A & B & 57 & \text{0B}[X]
\end{array}
\]

- Let XT be the value TX concatenated with T.
- Let XA be the value AX concatenated with A.
- Let XB be the value BX concatenated with B.

For **xsmsubadp**, do the following.
- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src1 is multiplied\(^1\) by src3, producing a product having unbounded range and precision.

See part 1 of Table 66.

src2 is negated and added\(^2\) to the product, producing a sum having unbounded range and precision.

The result, having unbounded range and precision, is normalized\(^3\).

See part 2 of Table 66.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are undefined.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 50, “Scalar Floating-Point Final Result,” on page 403.

Explanation:
src1: The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2: For `xsmsubadp`, the double-precision floating-point value in doubleword element 0 of VSR[XT].
src3: For `xsmsubadp`, the double-precision floating-point value in doubleword element 0 of VSR[XB].
src3: For `xsmsubdmp`, the double-precision floating-point value in doubleword element 0 of VSR[XT].
doQNaN: Default quiet NaN (0x7F8_0000_0000_0000).
NZF: Nonzero finite number.
Rezd: Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x): Return a QNaN with the payload of x.
S(x,y): Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision.
Note: If x = y, v is considered to be an exact-zero-difference result (Rezd).
M(x,y): Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
p: The intermediate product having unbounded range and precision.
v: The intermediate result having unbounded range and precision.
For \texttt{xsmsubasp}, do the following.
- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For \texttt{xsmsubmsp}, do the following.
- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied\textsuperscript{[1]} by src3, producing a product having unbounded range and precision.

See part 1 of Table 67, “Actions for \texttt{xmsub(a|m)sp}”.

src2 is negated and added\textsuperscript{[2]} to the product, producing a sum having unbounded range and precision.

The result, having unbounded range and precision, is normalized\textsuperscript{[3]}.

See part 2 of Table 67, “Actions for \texttt{xmsub(a|m)sp}”.

The intermediate result is rounded to single-precision using the rounding mode specified by RN.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are undefined.

FPRF is set to the class and sign of the result as represented in single-precision format. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 50, “Scalar Floating-Point Final Result,” on page 403.

---

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src1 is multiplied\(^1\) by src2, producing a product having unbounded range and precision.

The product is normalized\(^2\).

See Table 68.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

---

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

<th>XB</th>
</tr>
</thead>
<tbody>
<tr>
<td>60</td>
<td>T</td>
<td>A</td>
</tr>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
</tr>
</tbody>
</table>

*Let XT be the value TX concatenated with T.*

*Let XA be the value AX concatenated with A.*

*Let XB be the value BX concatenated with B.

**reset_xflags()**

- `src1` ← VSR[XA](0:63)
- `src2` ← “xsnmaddadp” ? VSR[XT](0:63) : VSR[XB](0:63)
- `src3` ← “xsnmaddadp” ? VSR[XB](0:63) : VSR[XT](0:63)
- `v[0:inf]` ← MultiplyAddDP(src1,src3,src2)
- `v[0:inf]` ← VSR[XT](0:63)
- `FR` ← ClassDP(result)
- `FI` ← inc_flag
- `vex_flag` ← VE & (vxsnan_flag | vximz_flag | vxisi_flag)

- If `~vex_flag` then do
  - `VSR[XT]` ← result || 0xUUUU_UUUU_UUUU_UUUU
  - `FPRF` ← ClassDP(result)
  - `FR` ← inc_flag
  - `FI` ← xx_flag
- Else do
  - `FR` ← 0
  - `FI` ← 0
- End

For **xsnmaddadp**, do the following.

- Let `src2` be the double-precision floating-point value in doubleword element 0 of VSR[XB].
- Let `src3` be the double-precision floating-point value in doubleword element 0 of VSR[XT].

`src1` is multiplied\(^1\) by `src3`, producing a product having unbounded range and precision.

See part 1 of Table 70.

`src2` is added\(^2\) to the product, producing a sum having unbounded range and precision.

The sum is normalized\(^3\).

See part 2 of Table 70.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

The result is negated and placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 0 of VSR[XT] are undefined.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 71, “Scalar Floating-Point Final Result with Negation,” on page 453.

---

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significant accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

### Explanation:

- **src1** The double-precision floating-point value in doubleword element 0 of VSR[XA].
- **src2** For *xsnmaddap*, the double-precision floating-point value in doubleword element 0 of VSR[XT].
- **src3** For *xsnmaddap*, the double-precision floating-point value in doubleword element 0 of VSR[XB].
- **dQNaN** Default quiet NaN (0x7FF8_0000_0000_0000).
- **NZF** Nonzero finite number.
- **Rezd** Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- **Q(x)** Return a QNaN with the payload of x.
- **A(x,y)** Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
- **M(x,y)** Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- **p** The intermediate product having unbounded range and precision.
- **v** The intermediate result having unbounded range and precision.

\end{array}\]

Explanation:

- The results do not depend on this condition.
- ClassFP(x) Classifies the floating-point value x as defined in Table 2, “Floating-Point Result Flags,” on page 327.
- fx(x) FX is set to 1 if x=0. x is set to 1.
- \(\beta\) Wrap adjust, where \(\beta = 2^{1536}\) for double-precision and \(\beta = 2^{192}\) for single-precision.
- q The value defined in Table 49, “Floating-Point Intermediate Result Handling,” on page 402, significand rounded to the target precision, unbounded exponent range.
- r The value defined in Table 49, “Floating-Point Intermediate Result Handling,” on page 402, significand rounded to the target precision, bounded exponent range.
- v The precise intermediate result defined in the instruction having unbounded significand precision, unbounded exponent range.
- FI Floating-Point Fraction Inexact status flag, FPSCR_FI. This status flag is nonsticky.
- FR Floating-Point Fraction Rounded status flag, FPSCR_FR.
- OX Floating-Point Overflow Exception status flag, FPSCR_OX.
- error() The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode.
- N(x) The value x is is negated by complementing the sign bit of x.
- T(x) The value x is placed in element 0 of VSR[XT] in the target precision format.
- UX Floating-Point Underflow Exception status flag, FPSCR_UX.
- VXSNAN Floating-Point Invalid Operation Exception (SNaN) status flag, FPSCR_VXSNAN.
- VXIMZ Floating-Point Invalid Operation Exception (Infinity \times Zero) status flag, FPSCR_VXIMZ.
- VXISI Floating-Point Invalid Operation Exception (Infinity – Infinity) status flag, FPSCR_VXISI.
- XX Floating-Point Inexact Exception status flag, FPSCR_XX. The flag is a sticky version of FPSCR_FI. When FPSCR_FI is set to a new value, the new value of FPSCR_XX is set to the result of ORing the old value of FPSCR_XX with the new value of FPSCR_FI.

**Explanation:**

- The results do not depend on this condition.
- ClassFP(x) Classifies the floating-point value x as defined in Table 2, “Floating-Point Result Flags,” on page 327.
- fx(x) FX is set to 1 if x = 0. x is set to 1.
- \( \beta \) Wrap adjust, where \( \beta = 2^{1536} \) for double-precision and \( \beta = 2^{192} \) for single-precision.
- \( q \) The value defined in Table 49, “Floating-Point Intermediate Result Handling,” on page 402, significand rounded to the target precision, unbounded exponent range.
- \( r \) The value defined in Table 49, “Floating-Point Intermediate Result Handling,” on page 402, significand rounded to the target precision, bounded exponent range.
- \( v \) The precise intermediate result defined in the instruction having unbounded significand precision, unbounded exponent range.
- FI Floating-Point Fraction Inexact status flag, FPSCRFI.
- FR Floating-Point Fraction Rounded status flag, FPSCRFR.
- OX Floating-Point Overflow Exception status flag, FPSCRUX.
- error() The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode.
- N(x) The value x is is negated by complementing the sign bit of x.
- T(x) The value x is placed in element 0 of VSR[XT] in the target precision format.
- ux The contents of the remaining element(s) of VSR[XT] are undefined.
- UX Floating-Point Underflow Exception status flag, FPSCRUX.
- VXSNAN Floating-Point Invalid Operation Exception (SNan) status flag, FPSCRVXSNAN.
- VXIMZ Floating-Point Invalid Operation Exception (Infinity × Zero) status flag, FPSCRVXIMZ.
- VXISI Floating-Point Invalid Operation Exception (Infinity – Infinity) status flag, FPSCRVXISI.
- XX Floating-Point Inexact Exception status flag, FPSCRXX. The flag is a sticky version of FPSCRXX. When FPSCRXX is set to a new value, the new value of FPSCRXX is set to the result of ORing the old value of FPSCRXX with the new value of FPSCRXX.

Table 71.Scalar Floating-Point Final Result with Negation (Continued)
VSX Scalar Negative Multiply-Add
Single-Precision XX3-form

For \texttt{xsnmaddasp}, do the following.
- Let \texttt{src1} be the double-precision floating-point value in doubleword element 0 of \texttt{VSR[XA]}.
- Let \texttt{src2} be the double-precision floating-point value in doubleword element 0 of \texttt{VSR[XT]}.
- Let \texttt{src3} be the double-precision floating-point value in doubleword element 0 of \texttt{VSR[XB]}.

\texttt{src1} is multiplied\textsuperscript{1} by \texttt{src3}, producing a product having unbounded range and precision.

See part 1 of Table 72, “Actions for \texttt{xsnmadd(a|m)sp},” on page 457.

\texttt{src2} is added\textsuperscript{2} to the product, producing a sum having unbounded range and precision.

The sum is normalized\textsuperscript{3}.

See part 2 of Table 72, “Actions for \texttt{xsnmadd(a|m)sp},” on page 457.

The intermediate result is rounded to single-precision using the rounding mode specified by \texttt{RN}.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

The result is negated and placed into doubleword element 0 of \texttt{VSR[XT]} in double-precision format.

The contents of doubleword element 1 of \texttt{VSR[XT]} are undefined.

\texttt{FPRF} is set to the class and sign of the result as represented in single-precision format. \texttt{FR} is set to indicate if the result was incremented when rounded. \texttt{FI} is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, \texttt{VSR[XT]} and \texttt{FPRF} are not modified, and \texttt{FR} and \texttt{FI} are set to 0.

See Table 71, “Scalar Floating-Point Final Result with Negation,” on page 453.

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

For \texttt{xsnmsubdmp}, do the following.
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied\(^1\) by src3, producing a product having unbounded range and precision.

See part 1 of Table 73.

src2 is negated and added\(^2\) to the product, producing a sum having unbounded range and precision.

The sum is normalized\(^3\).

See part 2 of Table 73.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

The result is negated and placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are undefined.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 71, “Scalar Floating-Point Final Result with Negation,” on page 453.

Explanation:
src The double-precision floating-point value in doubleword element 0 of VSR[XB].
dQNaN Default quiet NaN (0x7FF8_0000_0000_0000).
NZF Nonzero finite number.
SQRT(x) The unbounded-precision and exponent range square root of the floating-point value x.
Q(x) Return a QNaN with the payload of x.
v The intermediate result having unbounded significand precision and unbounded exponent range.

Table 76 Actions for xssqrtsp
**VSX Scalar Subtract Double-Precision XX3-form**

Let XT be the value TX concatenated with T. Let XA be the value AX concatenated with A. Let XB be the value BX concatenated with B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src2 is negated and added\(^1\) to src1, producing a sum having unbounded range and precision.

See Table 77.

The sum is normalized\(^2\).

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

---

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:

src1 The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2 The double-precision floating-point value in doubleword element 0 of VSR[XB].
dQNaN Default quiet NaN (0x7FF8_0000_0000_0000).
NZF Nonzero finite number.
Rezd Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).
S(x,y) Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision.
Note: If x = y, v is considered to be an exact-zero-difference result (Rezd).
Q(x) Return a QNaN with the payload of x.
v The intermediate result having unbounded significand precision and unbounded exponent range.

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src2 is negated and added[1] to src1, producing the sum, v, having unbounded range and precision.

See Table 78, “Actions for xssubsp,” on page 478.

v is normalized[2] and rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

---

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

</tbody>
</table>

**Explanation:**
- The results do not depend on this condition.
- `fx(x)` FX is set to 1 if `x=0`. `x` is set to 1.
- `q` The value defined in Table 49, “Floating-Point Intermediate Result Handling,” on page 402, significand rounded to the target precision, unbounded exponent range.
- `r` The value defined in Table 49, “Floating-Point Intermediate Result Handling,” on page 402, significand rounded to the target precision, bounded exponent range.
- `v` The precise intermediate result defined in the instruction having unbounded significand precision, unbounded exponent range.
- `OX` Floating-Point Overflow Exception status flag, FPSCR_OX.
- `error()` The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode. Update of the target VSR is suppressed for all vector elements.
- `T(x)` The value `x` is placed in element `i` of VSR[XT] in the target precision format (where `i \in \{0,1\}` for results with 64-bit elements, and `i \in \{0,1,3,4\}` for results with 32-bit elements).
- `UX` Floating-Point Underflow Exception status flag, FPSCR_UX.
- `VXSnan` Floating-Point Invalid Operation Exception (SNaN) status flag, FPSCR_VXSnan.
- `VXsOrt` Floating-Point Invalid Operation Exception (Invalid Square Root) status flag, FPSCR_VXsOrt.
- `VXidi` Floating-Point Invalid Operation Exception (Infinity ÷ Infinity) status flag, FPSCR_VXidi.
- `VXimi` Floating-Point Invalid Operation Exception (Infinity × 0) status flag, FPSCR_VXimi.
- `VXisi` Floating-Point Invalid Operation Exception (Infinity – Infinity) status flag, FPSCR_VXisi.
- `VXzdZ` Floating-Point Invalid Operation Exception (Zero ÷ Zero) status flag, FPSCR_VXzdZ.
- `XX` Floating-Point Inexact Exception status flag, FPSCR_XX. The flag is a sticky version of FPSCR_XX. When FPSCR_XX is set to a new value, the new value of FPSCR_XX is set to the result of ORing the old value of FPSCR_XX with the new value of FPSCR_XX.
- `ZX` Floating-Point Zero Divide Exception status flag, FPSCR_ZX.
VSX Vector Add Single-Precision XX3-form

The VSX Vector Add Single-Precision instruction, `vaddsp XT,XA,XB`, is defined as follows:

### Instruction Details

- **Operation**: Adds single-precision floating-point operands from `VSR[XA]` and `VSR[XB]` and stores the result in `VSR[XT]`.
- **Syntax**: `vaddsp XT,XA,XB`
- **Description**: For each vector element `i` from 0 to 127 by 32:

  - Let `src1` be the single-precision floating-point operand in word element `i` of `VSR[XA]`.
  - Let `src2` be the single-precision floating-point operand in word element `i` of `VSR[XB]`.
  - `src2` is added to `src1`, producing a sum having unbounded range and precision.
  - The sum is normalized.
  - The intermediate result is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

### Functionality

- **Special Registers Altered**:
  - FX, OX, UX, XX, VXSNAN, VXISI

### Notes

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

</tbody>
</table>

**Explanation:**

src1 The single-precision floating-point value in word element i of VSR[XA] (where i ∈ \{0,1,2,3\}).

src2 The single-precision floating-point value in word element i of VSR[XB] (where i ∈ \{0,1,2,3\}).

dQNaN Default quiet NaN (0x7FC0_0000).

NZF Nonzero finite number.

Rezd Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).

A(x,y) Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.

Note: If x = -y, v is considered to be an exact-zero-difference result (Rezd).

Q(x) Return a QNaN with the payload of x.

v The intermediate result having unbounded significand precision and unbounded exponent range.

Let XT be the value TX concatenated with T.

Let XA be the value AX concatenated with A.

Let XB be the value BX concatenated with B.

For each vector element i from 0 to 3, do the following.

Let src1 be the single-precision floating-point operand in word element i of VSR[XA].

Let src2 be the single-precision floating-point operand in word element i of VSR[XB].

src1 is compared to src2.

The contents of word element i of VSR[XT] are set to all 1s if src1 is greater than src2, and is set to all 0s otherwise.

A NaN input causes the comparison to return false for that element.

Two zero inputs of same or different signs return false for that element.

If Rc=1, CR Field 6 is set as follows.

- Bit 0 of CR[6] is set to indicate all vector elements compared true.
- Bit 1 of CR[6] is set to 0.
- Bit 2 of CR[6] is set to indicate all vector elements compared false.
- Bit 3 of CR[6] is set to 0.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT] and the contents of CR[6] are undefined if Rc is equal to 1.

**Explanation:**

- ConvertDPtoUW(x) The double-precision floating-point integer value x converted to unsigned integer word format.
- fx(x) FX is set to 1 if x=0. x is set to 1.
- error() The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode.
- Update of VSR[XT] is suppressed.
- Nmin The smallest unsigned integer word value, 0 (0x0000_0000).
- Nmax The largest unsigned integer word value, $2^{32} - 1$ (0xFFFF_FFFF).
- RoundToDPIntegerTrunc(x) The double-precision floating-point value x rounded to an integer using the rounding mode Round towards Zero.
- src The double-precision floating-point value in doubleword element i of VSR[XB] (where i ∈ {0, 1}).
- T(x) The unsigned integer word value x is placed in word element i of VSR[XT] (where i ∈ {0, 2}).

Let XT be the value TX concatenated with T.
Let XB be the value BX concatenated with B.

For each vector element i from 0 to 1, do the following.
  Let src be the single-precision floating-point operand in word element i×2 of VSR[XB].
  If src is a NaN, the result is the value 0x8000_0000_0000_0000 and VXCVI is set to 1. If src is an SNaN, VXSNAN is also set to 1.
  Otherwise, src is rounded to a floating-point integer using the rounding mode Round Toward Zero.
  If the rounded value is greater than 2^{63}-1, the result is 0x7FFF_FFFF_FFFF_FFFF and VXCVI is set to 1.
  Otherwise, if the rounded value is less than -2^{63}, the result is 0x8000_0000_0000_0000 and VXCVI is set to 1.
  Otherwise, the result is the rounded value converted to 64-bit signed-integer format.
  The result is placed into doubleword element i of VSR[XT].

See Table 87.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

### Explanation:

- **ConvertSPtoSD(x)**: The single-precision floating-point integer value x converted to signed integer doubleword format.
- **fx(x)**: FX is set to 1 if x=0. x is set to 1.
- **error()**: The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode.
- **Update of VSR[XT] is suppressed.**
- **Nmin**: The smallest signed integer doubleword value, $-2^{63}$ (0x8000_0000_0000_0000).
- **Nmax**: The largest signed integer doubleword value, $2^{63}-1$ (0x7FFF_FFFF_FFFF_FFFF).
- **RoundToSPIntegerTrunc(x)**: The single-precision floating-point value x rounded to an integer using the rounding mode Round towards Zero.
- **src**: The single-precision floating-point value in word element i of VSR[XB] (where i ∈ (0,2)).
- **T(x)**: The signed integer doubleword value x is placed in doubleword element i of VSR[XT] (where i ∈ (0,1)).

### Table 88. Actions for xcvspxsdxds

</tbody>
</table>

- Let XT be the value TX concatenated with T.
- Let XB be the value BX concatenated with B.

For each vector element i from 0 to 3, do the following.

#### Programming Note

**xvcvspsxws** rounds using Round towards Zero rounding mode. For other rounding modes, software must use a *Round to Single-Precision Integer* instruction that corresponds to the desired rounding mode, including **xvrspic** which uses the rounding mode specified by the RN field in the FPSCR.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

\text{end}
\]

\[
\text{if( ex_flag = 0 ) then VSR[XT] } \leftarrow \text{result}
\]

Let **XT** be the value TX concatenated with T.
Let **XB** be the value BX concatenated with B.

For each vector element \( i \) from 0 to 3, do the following.

Let \( \text{src} \) be the single-precision floating-point operand in word element \( i \) of VSR[**XB**].

If \( \text{src} \) is a NaN, the result is the value 0x0000_0000 and VXCVI is set to 1. If \( \text{src} \) is an SNaN, VXSNAN is also set to 1.

Otherwise, \( \text{src} \) is rounded to a floating-point integer using the rounding mode Round Toward Zero.

If the rounded value is greater than \( 2^{32}-1 \), the result is 0xFFFF_FFFF and VXCVI is set to 1.

Otherwise, if the rounded value is less than 0, the result is 0x0000_0000 and VXCVI is set to 1.

Otherwise, the result is the rounded value converted to 32-bit unsigned-integer format.

The result is placed into word element \( i \) of VSR[**XT**].

See Table 87.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[**XT**].

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

For each vector element i from 0 to 1, do the following.
Let srcl be the double-precision floating-point operand in doubleword element i of VSR[XA].

Let srcl be the double-precision floating-point operand in doubleword element i of VSR[XB].

srcl is divided[1] by srcl2, producing a quotient having unbounded range and precision.

The quotient is normalized[2].

See Table 92.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

---

1. Floating-point division is based on exponent subtraction and division of the significands.
2. Floating-point normalization is based on shifting the significant left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significant was shifted.

Explanation:
- src1 The double-precision floating-point value in doubleword element i of VSR[XA] (where i ∈ {0,1}).
- src2 The double-precision floating-point value in doubleword element i of VSR[XB] (where i ∈ {0,1}).
- dQNaN Default quiet NaN (0x7FF8_0000_0000_0000).
- NZF Nonzero finite number.
- Rezd Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).
- D(x,y) Return the normalized quotient of floating-point value x divided by floating-point value y, having unbounded range and precision.
- Q(x) Return a QNaN with the payload of x.
- v The intermediate result having unbounded significand precision and unbounded exponent range.
### VSX Vector Divide Single-Precision XX3-form

The VSX Vector Divide Single-Precision XX3-form (`xdivsp XT,XA,XB`) performs floating-point division on single-precision elements of two vectors `XA` and `XB`, and stores the results in vector `XT`. Here's a breakdown of the operation:

1. **Input Vectors**:
   - `XT`: The result vector, where the elements are to be stored.
   - `XA`: The first operand vector.
   - `XB`: The second operand vector.

2. **Operation Details**:
   - For each vector element `i` from 0 to 127, the following steps are performed:
     - Let `src1` be the single-precision floating-point operand in word element `i` of `VSR[XA]`.
     - Let `src2` be the single-precision floating-point operand in word element `i` of `VSR[XB]`.
     - `src1` is divided by `src2`, producing a quotient with unbounded range and precision.
     - The quotient is normalized.
     - The intermediate result is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field `RN` of the FPSCR.

3. **Result Handling**:
   - The result is placed into word element `i` of `VSR[XT]` in single-precision format.

4. **Exception Handling**:
   - If a trap-enabled exception occurs in any element of the vector, no results are written to `VSR[XT].`

Explanation:
- src1: The single-precision floating-point value in word element i of VSR[XA] (where i ∈ {0,1,2,3}).
- src2: The single-precision floating-point value in word element i of VSR[XB] (where i ∈ {0,1,2,3}).
- dQNaN: Default quiet NaN (0x7FC0_0000).
- NZF: Nonzero finite number.
- Rezd: Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).
- D(x,y): Return the normalized quotient of floating-point value x divided by floating-point value y, having unbounded range and precision.
- Note: If x = -y, v is considered to be an exact-zero-difference result (Rezd).
- Q(x): Return a QNaN with the payload of x.
- v: The intermediate result having unbounded significand precision and unbounded exponent range.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

**Special Registers Altered**

FX OX UX XX VXSNAN VXISI VXIMZ

For **xvmaddadp**, do the following.
- Let **src1** be the double-precision floating-point operand in doubleword element i of VSR[XA].
- Let **src2** be the double-precision floating-point operand in doubleword element i of VSR[XT].
- Let **src3** be the double-precision floating-point operand in doubleword element i of VSR[XB].

For **xvmaddmdp**, do the following.
- Let **src1** be the double-precision floating-point operand in doubleword element i of VSR[XA].
- Let **src2** be the double-precision floating-point operand in doubleword element i of VSR[XT].
- Let **src3** be the double-precision floating-point operand in doubleword element i of VSR[XB].

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

**Explanation:**

- **src1** The double-precision floating-point value in doubleword element i of VSR[XA] (where i ∈ {0,1}).
- **src2** For xvmadd dp, the double-precision floating-point value in doubleword element i of VSR[XT] (where i ∈ {0,1}).
- **src3** For xvmadd dp, the double-precision floating-point value in doubleword element i of VSR[XB] (where i ∈ {0,1}).
- **dQNaN** Default quiet NaN (Q=7F80_0000_0000_0000).
- **NZF** Nonzero finite number.
- **Rezd** Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- **Q(x)** Return the normalized QNaN with the payload of x.
- **A(x,y)** Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
  
  **Note:** If x = -y, v is considered to be an exact-zero-difference result (Rezd).
- **M(x,y)** Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- **p** The intermediate product having unbounded range and precision.
- **v** The intermediate result having unbounded range and precision.

**Table 94. Actions for xvmadd(dp)**
VSX Vector Multiply-Add Single-Precision XX3-form

For \textit{xvmaddasp}, do the following.

- Let \textit{src1} be the single-precision floating-point operand in word element \textit{i} of VSR[\(\text{XA}\)].
- Let \textit{src2} be the single-precision floating-point operand in word element \textit{i} of VSR[\(\text{XB}\)].
- Let \textit{src3} be the single-precision floating-point operand in word element \textit{i} of VSR[\(\text{XT}\)].

\textit{src1} is multiplied\(^1\) by \textit{src3}, producing a product having unbounded range and precision.

\textit{src2} is added\(^2\) to the product, producing a sum having unbounded range and precision.

The sum is normalized\(^3\).

See part 1 of Table 95.

The intermediate result is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

The result is placed into word element \textit{i} of VSR[\(\text{XT}\)] in single-precision format.

See Table 80, “Vector Floating-Point Final Result,” on page 484.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[\(\text{XT}\)].

\]

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

For each vector element i from 0 to 1, do the following.
Let src1 be the double-precision floating-point operand in doubleword element i of VSR[AX].

Let src2 be the double-precision floating-point operand in doubleword element i of VSR[XB].

If src1 is greater than src2, src1 is placed into doubleword element i of VSR[XT] in double-precision format. Otherwise, src2 is placed into doubleword element i of VSR[XT] in double-precision format.

The maximum of +0 and –0 is +0. The maximum of a QNaN and any value is that value. The maximum of any value and an SNaN when VE=0 is that SNaN converted to a QNaN.

See Table 96.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

For each vector element i from 0 to 3, do the following.

Let src1 be the single-precision floating-point operand in word element i of VSR[XA].

Let src2 be the single-precision floating-point operand in word element i of VSR[XB].

If src1 is greater than src2, src1 is placed into word element i of VSR[XT] in single-precision format. Otherwise, src2 is placed into word element i of VSR[XT] in single-precision format.

The maximum of +0 and −0 is +0. The maximum of a QNaN and any value is that value. The maximum of any value and an SNaN when VE=0 is that SNaN converted to a QNaN.

See Table 97.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

<td>\text{xvmsubadp}</td>
<td>XT,XA,XB</td>
</tr>
</tbody>
</table>

| XT | ← TX || T |
| XA | ← AX || A |
| XB | ← BX || B |
| ex_flag | ← 0b0 |

For \text{xvmsubadp}, do the following.

- Let \text{src1} be the double-precision floating-point operand in doubleword element \(i\) of VSR[ZA].
- Let \text{src2} be the double-precision floating-point operand in doubleword element \(i\) of VSR[ZB].
- Let \text{src3} be the double-precision floating-point operand in doubleword element \(i\) of VSR[XZ].

\text{src1} is multiplied\(^1\) by \text{src3}, producing a product having unbounded range and precision.

\text{src2} is negated and added\(^2\) to the product, producing a sum having unbounded range and precision.

The sum is normalized\(^3\).

See part 1 of Table 100.

See part 2 of Table 100.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

The result is placed into doubleword element \(i\) of VSR[XZ] in double-precision format.

See Table 80, “Vector Floating-Point Final Result,” on page 484.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XZ].

---

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

**Explanation:**

- **src1:** The double-precision floating-point value in doubleword element i of `VSR[XT]` (where i ∈ (0, 1)).
- **src2:** For `xvmsubadp`, the double-precision floating-point value in doubleword element i of `VSR[XA]` (where i ∈ (0, 1)).
- **src3:** For `xvmsubadp`, the double-precision floating-point value in doubleword element i of `VSR[XB]` (where i ∈ (0, 1)).
- **dQNaN:** Default quiet NaN (`QNaN00_0000_0000_0000`).
- **NZF:** Nonzero finite number.
- **Rezd:** Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number operands.
- **Q(x):** Return a QNaN with the payload of x.
- **S(x, y):** Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision.
  - **Note:** If x = y, v is considered to be an exact-zero-difference result (Rezd).
- **M(x, y):** Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- **p:** The intermediate product having unbounded range and precision.
- **v:** The intermediate result having unbounded range and precision.
VSX Vector Multiply-Subtract Single-Precision XX3-form

For **xvmsubasp**, do the following.
- Let $src_1$ be the single-precision floating-point operand in word element $i$ of VSR[XA].
- Let $src_2$ be the single-precision floating-point operand in word element $i$ of VSR[XB].
- Let $src_3$ be the single-precision floating-point operand in word element $i$ of VSR[XT].

For **xvmsubmsp**, do the following.
- Let $src_1$ be the single-precision floating-point operand in word element $i$ of VSR[XA].
- Let $src_2$ be the single-precision floating-point operand in word element $i$ of VSR[XB].
- Let $src_3$ be the single-precision floating-point operand in word element $i$ of VSR[XT].

Let $XT$ be the value $TX$ concatenated with $T$.
Let $XA$ be the value $AX$ concatenated with $A$.
Let $XB$ be the value $BX$ concatenated with $B$.

For each vector element $i$ from 0 to 3, do the following.

For **xvmsubasp**, do the following.
- Let $src_1$ be the single-precision floating-point operand in word element $i$ of VSR[XA].
- Let $src_2$ be the single-precision floating-point operand in word element $i$ of VSR[XT].
- Let $src_3$ be the single-precision floating-point operand in word element $i$ of VSR[XB].

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits ($G$, $R$, and $X$) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

For each vector element i from 0 to 1, do the following.

Let src1 be the double-precision floating-point
operand in doubleword element i of VSR[XA].

Let src2 be the double-precision floating-point
operand in doubleword element i of VSR[XB].

src1 is multiplied\(^1\) by src2, producing a product
having unbounded range and precision.

The product is normalized\(^2\).

See Table 102.

The intermediate result is rounded to
double-precision using the rounding mode
specified by the Floating-Point Rounding Control
field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result
Handling,” on page 402.

---

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

VSX Vector Negative Multiply-Add
Double-Precision XX3-form

For `xvnmmaddp`, do the following.
- Let `src1` be the double-precision floating-point operand in doubleword element `i` of VSR[XA].
- Let `src2` be the double-precision floating-point operand in doubleword element `i` of VSR[XB].
- Let `src3` be the double-precision floating-point operand in doubleword element `i` of VSR[XT].

`src1` is multiplied\(^1\) by `src3`, producing a product having unbounded range and precision.

See part 1 of Table 104.

`src2` is added\(^2\) to the product, producing a sum having unbounded range and precision.

The sum is normalized\(^3\).

See part 2 of Table 104.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

The result is negated and placed into doubleword element `i` of VSR[XT] in double-precision format.

See Table 105, “Vector Floating-Point Final Result with Negation,” on page 550.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

Special Registers Altered

  FX OX UX XX VXSNaN VXISI VXIMZ
```

Floating-point multiplication is based on exponent addition and multiplication of the significands.

Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

---

**Explanation:**

- **src1:** The double-precision floating-point value in doubleword element \( i \) of VSR[XA] (where \( i \in (0,1) \)).
- **src2:** For `vxnmmadddp`, the double-precision floating-point value in doubleword element \( i \) of VSR[XT] (where \( i \in (0,1) \)).
- **src3:** For `vxnmmadddp`, the double-precision floating-point value in doubleword element \( i \) of VSR[XB] (where \( i \in (0,1) \)).
- **dONaN:** Default quiet NaN \((0x07F8_0000_0000_0000)\).
- **NZF:** Nonzero finite number.
- **Rezd:** Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number operand.
- **Q(x):** Return a QNaN with the payload of \( x \).
- **A(x,y):** Return the normalized sum of floating-point value \( x \) and floating-point value \( y \), having unbounded range and precision.
- **M(x,y):** Return the product of floating-point value \( x \) and floating-point value \( y \), having unbounded range and precision.
- **p:** The intermediate product having unbounded range and precision.
- **v:** The intermediate result having unbounded range and precision.

- fx(VXSNAN), fx(VXIMZ), error()
- fx(VXISI), error()
- fx(VXIMZ), error()
- fx(VXSNAN), error()
- fx(VXSNAN), fx(VXIMZ), error()
- fx(VXISI), error()
- fx(VXIMZ), error()
- fx(VXSNAN), error()
- fx(VXSNAN), fx(VXIMZ), error()

**Explanation:**

- The results do not depend on this condition.
- FX is set to 1 if \(x=0\). \(x\) is set to 1.
- The value defined in Table 49, “Floating-Point Intermediate Result Handling,” on page 402, significand rounded to the target precision, unbounded exponent range.
- The value defined in Table 49, “Floating-Point Intermediate Result Handling,” on page 402, significand rounded to the target precision, bounded exponent range.
- The precise intermediate result defined in the instruction having unbounded significand precision, unbounded exponent range.
- Floating-Point Fraction Inexact status flag, FPSCR\_IF. This status flag is nonsticky.
- Floating-Point Fraction Rounded status flag, FPSCR\_FR.
- Floating-Point Overflow Exception status flag, FPSCR\_OX.
- The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode. Update of the target VSR is suppressed for all vector elements.
- The value \(x\) is is negated by complementing the sign bit of \(x\).
- The value \(x\) is placed in element i of VSR[\(XT\)] in the target precision format (where i \(\in\{0,1\}\) for results with 64-bit elements, and i \(\in\{0,1,3,4\}\) for results with 32-bit elements).
- Floating-Point Underflow Exception status flag, FPSCR\_UX.
- Floating-Point Invalid Operation Exception (SNAN) status flag, FPSCR\_VXSNAN.
- Floating-Point Invalid Operation Exception (Infinity \(\times\) Zero) status flag, FPSCR\_VXIMZ.
- Floating-Point Invalid Operation Exception (Infinity \(\div\) Infinity) status flag, FPSCR\_VXISI.
- Floating-Point Inexact Exception status flag, FPSCR\_XX. The flag is a sticky version of FPSCR\_F. When FPSCR\_F is set to a new value, the new value of FPSCR\_XX is set to the result of ORing the old value of FPSCR\_XX with the new value of FPSCR\_F.

**Table 105. Vector Floating-Point Final Result with Negation**
Chapter 7. Vector-Scalar Floating-Point Operations [Category: VSX] 551

Table 105. Vector Floating-Point Final Result with Negation (Continued)
**VSX Vector Negative Multiply-Add**

**Single-Precision XX3-form**

For **vxnmadmsp**, do the following.
- Let **src1** be the single-precision floating-point operand in word element i of VSR[XA].
- Let **src2** be the single-precision floating-point operand in word element i of VSR[XB].
- Let **src3** be the single-precision floating-point operand in word element i of VSR[XT].

**src1** is multiplied[1] by **src3**, producing a product having unbounded range and precision.

See part 1 of Table 106.

**src2** is added[2] to the product, producing a sum having unbounded range and precision.

The sum is normalized[3].

See part 2 of Table 106.

The intermediate result is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

The result is negated and placed into word element i of VSR[XT] in single-precision format.

See Table 105, “Vector Floating-Point Final Result with Negation,” on page 550.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

ex_flag ← ex_flag | (VE & xx_flag)
end
if( ex_flag = 0 ) then VSR[XT] ← result

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

**Explanation:**

- **src1** The single-precision floating-point value in word element i of VSR[XA] (where i \( \in \{0,1,2,3\} \)).
- **src2** For xvnmaddasp, the single-precision floating-point value in word element i of VSR[XT] (where i \( \in \{0,1,2,3\} \)).
- **src3** For xvnmaddasp, the single-precision floating-point value in word element i of VSR[XB] (where i \( \in \{0,1,2,3\} \)).
- For \texttt{xvnmaddmsp}, the single-precision floating-point value in word element i of VSR[XBT] (where i \( \in \{0,1,2,3\} \)).
- dQNaN Default quiet NaN (0x7FC0_0000).
- NZF Nonzero finite number.
- Rezd Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- Q(x) Return a QNaN with the payload of x.
- A(x,y) Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
  - Note: If x = –y, v is considered to be an exact-zero-difference result (Rezd).
- M(x,y) Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- p The intermediate product having unbounded range and precision.
- v The intermediate result having unbounded range and precision.

\]

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

For each vector element i from 0 to 1, do the following.

For \text{xnmsubadp}, do the following.
- Let src1 be the double-precision floating-point operand in doubleword element i of VSR[XA].
- Let src2 be the double-precision floating-point operand in doubleword element i of VSR[XT].
- Let src3 be the double-precision floating-point operand in doubleword element i of VSR[XB].

src1 is multiplied\(^1\) by src3, producing a product having unbounded range and precision.

See part 1 of Table 107.

src2 is negated and added\(^2\) to the product, producing a sum having unbounded range and precision.

The sum is normalized\(^3\).

See part 2 of Table 107.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

The result is negated and placed into doubleword element i of VSR[XT] in double-precision format.

See Table 105, “Vector Floating-Point Final Result with Negation,” on page 550.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

Explanation:

src1 The double-precision floating-point value in doubleword element i of VSR[XA] (where i ∈ [0,1]).
src2 For xvnmsubdp, the double-precision floating-point value in doubleword element i of VSR[XT] (where i ∈ [0,1]).
src3 For xvnmsubadp, the double-precision floating-point value in doubleword element i of VSR[XB] (where i ∈ [0,1]).
dQNaN Default quiet NaN (x97F8_0000_0000_0000).
NZF Nonzero finite number.
Rezd Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number operands.
Q(x) Return a QNaN with the payload of x.
S(x,y) Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision.
Note: If x = -y, v is considered to be an exact-zero-difference result (Rezd).
M(x,y) Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
p The intermediate product having unbounded range and precision.
v The intermediate result having unbounded range and precision.
VSX Vector Negative Multiply-Subtract Single-Precision XX3-form

do i=0 to 127 by 32

if( ex_flag = 0 ) then VSR[XT] ← result

For xvnmsubasp, do the following.
– Let src1 be the single-precision floating-point operand in word element i of VSR[XA].
– Let src2 be the single-precision floating-point operand in word element i of VSR[XB].
– Let src3 be the single-precision floating-point operand in word element i of VSR[XT].

src1 is multiplied\(^1\) by src3, producing a product having unbounded range and precision.

See part 1 of Table 108.

src2 is negated and added\(^2\) to the product, producing a sum having unbounded range and precision.

The sum is normalized\(^3\).

See part 2 of Table 108.

The intermediate result is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

The result is negated and placed into word element i of VSR[XT] in single-precision format.

See Table 105, “Vector Floating-Point Final Result with Negation,” on page 550.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

Special Registers Altered
FX OX UX XX VXSNAN VXISI VXIMZ

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

For each vector element i from 0 to 3, do the following.

For xvnmsubasp, do the following.
– Let src1 be the single-precision floating-point operand in word element i of VSR[XA].
– Let src2 be the single-precision floating-point operand in word element i of VSR[XB].
– Let src3 be the single-precision floating-point operand in word element i of VSR[XT].

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

### Explanation:

- **src1**: The single-precision floating-point value in word element i of VSR[XT] (where i ∈ {0,1,2,3}).
- **src2**: The single-precision floating-point value in word element i of VSR[XT] (where i ∈ {0,1,2,3}).
- **src3**: The single-precision floating-point value in word element i of VSR[XB] (where i ∈ {0,1,2,3}).
- **dQNaN**: Default quiet NaN (0x7FC0_0000).
- **NZF**: Nonzero finite number.
- **Rezd**: Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- **Q(x)**: Return a QNaN with the payload of x.
- **S(x,y)**: Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision.
  - **Note**: If x = –y, v is considered to be an exact-zero-difference result (Rezd).
- **M(x,y)**: Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- **p**: The intermediate product having unbounded range and precision.
- **v**: The intermediate result having unbounded range and precision.

**Explanation:**

- **src** The double-precision floating-point value in doubleword element i of VSR[XB] (where i ∈ (0,1)).
- **dQNaN** Default quiet NaN (0x7FF8_0000_0000_0000).
- **NZF** Nonzero finite number.
- **SQRT(x)** The unbounded-precision square root of the floating-point value x.
- **Q(x)** Return a QNaN with the payload of x.
- **v** The intermediate result having unbounded significand precision and unbounded exponent range.

**Table 109: Actions for xvsqrtdp**
VSX Vector Square Root Single-Precision
XX2-form

Let XT be the value TX concatenated with T.
Let XB be the value BX concatenated with B.

For each vector element i from 0 to 3, do the following.

Let src be the single-precision floating-point operand in word element i of VSR[XB].

The unbounded-precision square root of src is produced.

See Table 110.

The intermediate result is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

The result is placed into word element i of VSR[XT] in single-precision format.

See Table 80, “Vector Floating-Point Final Result,” on page 484.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

end

if( ex_flag ) then VSR[XT] ← result

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

For each vector element i from 0 to 1, do the following.
Let src1 be the double-precision floating-point operand in doubleword element i of VSR[XA].

Let src2 be the double-precision floating-point operand in doubleword element i of VSR[XB].

src2 is negated and added\(^1\) to src1, producing a sum having unbounded range and precision.

The sum is normalized\(^2\).

See Table 111.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, "Floating-Point Intermediate Result Handling," on page 402.

---

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

For each vector element i from 0 to 3, do the following.
Let src1 be the single-precision floating-point operand in word element i of VSR[XA].
Let src2 be the single-precision floating-point operand in word element i of VSR[XB].

src2 is negated and added[1] to src1, producing a sum having unbounded range and precision.
The sum is normalized[2].

See Table 112.

The intermediate result is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 49, “Floating-Point Intermediate Result Handling,” on page 402.

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:
src1 The single-precision floating-point value in word element i of VSR[XA] (where i ∈ (0,1,2,3)).
src2 The single-precision floating-point value in word element i of VSR[XB] (where i ∈ (0,1,2,3)).
dQNaN Default quiet NaN (0x7FC0_0000).
NZF Nonzero finite number.
NZF Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).
S(x,y) Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision.
Note: If x + y, v is considered to be an exact-zero-difference result (Rezd).
Q(x) Return a QNaN with the payload of x.
v The intermediate result having unbounded significand precision and unbounded exponent range.

Chapter 8. Signal Processing Engine (SPE)  
[Category: Signal Processing Engine]

8.1 Overview

The Signal Processing Engine (SPE) accelerates signal processing applications normally suited to DSP operation. This is accomplished using short vectors (two element) within 64-bit GPRs and using single instruction multiple data (SIMD) operations to perform the requisite computations. SPE also architects an Accumulator register to allow for back to back operations without loop unrolling.

8.2 Nomenclature and Conventions

Several conventions regarding nomenclature are used for SPE:

- The Signal Processing Engine category is abbreviated as SPE.
- Bits 0 to 31 of a 64-bit register are referenced as upper word, even word or high word element of the register. Bits 32:63 are referred to as lower word, odd word or low word element of the register. Each half is an element of a 64-bit GPR.
- Bits 0 to 15 and bits 32 to 47 are referenced as even halfwords. Bits 16 to 31 and bits 48 to 63 are referenced as odd halfwords.
- Mnemonics for SPE instructions generally begin with the letters ‘ev’ (embedded vector).

The RTL conventions in described below are used in addition to those described in Section 1.3: Additional RTL functions are described in Appendix D.

<table>

<td>x_sf</td>
<td>Signed fractional multiplication. Result of multiplying 2 signed fractional quantities having bit length n taking the least significant 2n-1 bits of the sign extended product and concatenating a 0 to the least significant bit forming a signed fractional result of 2n bits. Two 16-bit signed fractional quantities, a and b are multiplied, as shown below: ea_0:31 = EXTS(a) and eb_0:31 = EXTS(b) prod_0:63 = ea X eb eprod_0:63 = EXTS(prod_0:63) result_0:31 = eprod_33:63</td>
</tr>
</tbody>
</table>

Guarded signed fractional multiplication. Result of multiplying 2 signed fractional quantities having bit length 16 taking the least significant 31 bits of the sign extended product and concatenating a 0 to the least significant bit forming a guarded signed fractional result of 64 bits. Since guarded signed fractional multiplication produces a 64-bit result, fractional input quantities of -1 and -1 can produce +1 in the intermediate product. Two 16-bit fractional quantities, a and b are multiplied, as shown below:

ea\_0:31 = EXTS(a) and eb\_0:31 = EXTS(b) prod\_0:63 = ea X eb eprod\_0:63 = EXTS(prod\_0:63) result\_0:63 = eprod\_1:63 || 0b0

<< Logical shift left. x << y shifts value x left by y bits, leaving zeros in the vacated bits.

>> Logical shift right. x >> y shifts value x right by y bits, leaving zeros in the vacated bits.

8.3 Programming Model

8.3.1 General Operation

SPE instructions generally take elements from one source register and operate on them with the corresponding elements of a second source register (and/or the accumulator) to produce results. Results are placed in the destination register and/or the accumulator. Instructions that are vector in nature (i.e. produce results of more than one element) provide results for each element that are independent of the computation of the other elements. These instructions can also be used to perform scalar DSP operations by ignoring the results of the upper 32-bit half of the register file.
There are no record forms of SPE instructions. As a result, the meaning of bits in the CR is different than for other categories. SPE Compare instructions specify a CR field, two source registers, and the type of compare: greater than, less than, or equal. Two bits of the CR field are written with the result of the vector compare, one for each element. The remaining two bits reflect the ANDing and ORing of the vector compare results.

8.3.2 GPR Registers

The SPE requires a GPR register file with thirty-two 64-bit registers. For 32-bit implementations, instructions that normally operate on a 32-bit register file access and change only the least significant 32-bits of the GPRs leaving the most significant 32-bits unchanged. For 64-bit implementations, operation of these instructions is unchanged, i.e. those instructions continue to operate on the 64-bit registers as they would if the SPE was not implemented. Most SPE instructions view the 64-bit register as being composed of a vector of two elements, each of which is 32 bits wide (some instructions read or write 16-bit elements). The most significant 32-bits are called the upper word, high word or even word. The least significant 32-bits are called the lower word, low word or odd word. Unless otherwise specified, SPE instructions write all 64-bits of the destination register.

8.3.3 Accumulator Register

A partially visible accumulator register (ACC) is provided for some SPE instructions. The accumulator is a 64-bit register that holds the results of the Multiply Accumulate (MAC) forms of SPE Fixed-Point instructions. The accumulator allows the back-to-back execution of dependent MAC instructions, something that is found in the inner loops of DSP code such as FIR and FFT filters. The accumulator is partially visible to the programmer in the sense that its results do not have to be explicitly read to use them. Instead they are always copied into a 64-bit destination GPR which is specified as part of the instruction. Based upon the type of instruction, the accumulator can hold either a single 64-bit value or a vector of two 32-bit elements.
FXH represents the logical ‘or’ of all the bits shifted right from the Guard bit when the fractional result is normalized. FXH is zeroed if an overflow, underflow, or invalid input error is detected on the high element of an SPE.Embedded Float Vector instruction.

Execution of an SPE.Embedded Float Scalar instruction leaves FXH undefined.

36 Embedded Floating-Point Invalid Operation/Input Error High (FINVH) [Category: SP.FV]
The FINVH bit is set to 1 if any high word operand of an SPE.Embedded Float Vector instruction is infinity, NaN, or a denormalized value, or if the instruction is a divide and the dividend and divisor are both 0, or if a conversion to integer or fractional value overflows.

Execution of an SPE.Embedded Float Scalar instruction leaves FINVH undefined.

37 Embedded Floating-Point Divide By Zero High (FDBZH) [Category: SP.FV]
The FDBZH bit is set to 1 when an SPE.Embedded Vector Floating-Point Divide instruction is executed with a divisor of 0 in the high word operand, and the dividend is a finite nonzero number.

Execution of an SPE.Embedded Float Scalar instruction leaves FDBZH undefined.

38 Embedded Floating-Point Underflow High (FUNFH) [Category: SP.FV]
The FUNFH bit is set to 1 when the execution of an SPE.Embedded Float Vector instruction results in an underflow on the high word operation.

Execution of an SPE.Embedded Float Scalar instruction leaves FUNFH undefined.

39 Embedded Floating-Point Overflow High (FOVFH) [Category: SP.FV]
The FOVFH bit is set to 1 when the execution of an SPE.Embedded Float Vector instruction results in an overflow on the high word operation.

Execution of an SPE.Embedded Float Scalar instruction leaves FOVFH undefined.

40:41 Reserved

42 Embedded Floating-Point Inexact Sticky Flag (FINXS) [Categories: SP.FV, SP.FD, SP.FS]
The FINXS bit is set to 1 whenever the execution of an Embedded Floating-Point instruction delivers an inexact result for either the low or high element and no Embedded Floating-Point Data interrupt is taken for either element, or if an Embedded Floating-Point instruction results in overflow (FOVF=1 or FOVFH=1), but Embedded Floating-Point Overflow exceptions are disabled (FOVFE=0), or if an Embedded Floating-Point instruction results in underflow (FUNF=1 or FUNFH=1), but Embedded Floating-Point Underflow exceptions are disabled (FUNFE=0), and no Embedded Floating-Point Data interrupt occurs. This is a sticky bit.

43 Embedded Floating-Point Invalid Operation/Input Sticky Flag (FINVS) [Categories: SP.FV, SP.FD, SP.FS]
The FINVS bit is defined to be the sticky result of any Embedded Floating-Point instruction that causes FINVH or FINV to be set to 1. That is, FINVS ← FINVS | FINV | FINVH. This is a sticky bit.

44 Embedded Floating-Point Divide By Zero Sticky Flag (FDBZS) [Categories: SP.FV, SP.FD, SP.FS]
The FDBZS bit is set to 1 when an Embedded Floating-Point Divide instruction sets FDBZH or FDBZ to 1. That is, FDBZS ← FDBZS | FDBZ | FDBZH. This is a sticky bit.

45 Embedded Floating-Point Underflow Sticky Flag (FUNFS) [Categories: SP.FV, SP.FD, SP.FS]
The FUNFS bit is defined to be the sticky result of any Embedded Floating-Point instruction that causes FUNFH or FUNF to be set to 1. That is, FUNFS ← FUNFS | FUNF | FUNFH. This is a sticky bit.

46 Embedded Floating-Point Overflow Sticky Flag (FOVFS) [Categories: SP.FV, SP.FD, SP.FS]
The FOVFS bit is defined to be the sticky result of any Embedded Floating-Point instruction that causes FOVH or FOVF to be set to 1. That is, FOVFS ← FOVFS | FOVF | FOVFH. This is a sticky bit.

47 Summary Integer Overflow (SOV)
SOV is set to 1 when an SPE instruction sets OV to 1. This is a sticky bit.

48 Integer Overflow (OV)
OV is set to 1 to indicate that an overflow has occurred in the lower element during execution of an SPE instruction. The bit is set to 1 if a result of an operation performed by the instruction cannot be represented in the number of bits into which the result is to be placed, and is set to 0 otherwise. The OV bit is not altered by Modulo instructions, or by other instructions that cannot overflow.

49 Embedded Floating-Point Guard Bit (Low/scalar) (FG) [Categories: SP.FV, SP.FD, SP.FS]
FG is supplied for use by the Embedded Floating-Point Round interrupt handler. FG is an extension of the low-order bits of the fractional result produced from an Embedded Floating-Point instruction on the low word. FG is zeroed if an overflow, underflow, or invalid input error is detected on the low element of an Embedded Floating-Point instruction.

**51 Embedded Floating-Point Inexact Bit (Low/scalar)** (FX) [Categories: SP.FV, SPFD, SPFS]
FX is supplied for use by the Embedded Floating-Point Round interrupt handler. FX is an extension of the low-order bits of the fractional result produced from an Embedded Floating-Point instruction on the low word. FX represents the logical 'or' of all the bits shifted right from the Guard bit when the fractional result is normalized. FX is zeroed if an overflow, underflow, or invalid input error is detected on Embedded Floating-Point instruction.

**52 Embedded Floating-Point Invalid Operation/Input Error (Low/scalar)** (FINV) [Categories: SP.FV, SPFD, SPFS]
The FINV bit is set to 1 if any low word operand of an Embedded Floating-Point instruction is infinity, NaN, or a denormalized value, or if the operation is a divide and the dividend and divisor are both 0, or if a conversion to integer or fractional value overflows.

**53 Embedded Floating-Point Divide By Zero (Low/scalar)** (FDBZ) [Categories: SP.FV, SPFD, SPFS]
The FDBZ bit is set to 1 when an Embedded Floating-Point Divide instruction is executed with a divisor of 0 in the low word operand, and the dividend is a finite nonzero number.

**54 Embedded Floating-Point Underflow (Low/scalar)** (FUNF) [Categories: SP.FV, SPFD, SPFS]
The FUNF bit is set to 1 when the execution of an Embedded Floating-Point instruction results in an underflow on the low word operation.

**55 Embedded Floating-Point Overflow (Low/scalar)** (FOVF) [Categories: SP.FV, SPFD, SPFS]
The FOVF bit is set to 1 when the execution of an Embedded Floating-Point instruction results in an overflow on the low word operation.

**56 Reserved**

**57 Embedded Floating-Point Round (Inexact) Exception Enable** (FINXE) [Categories: SP.FV, SPFD, SPFS]

0 Exception disabled
1 Exception enabled

The Embedded Floating-Point Round interrupt is taken if the exception is enabled and if FG | FGH | FX | FXH (signifying an inexact result) is set to 1 as a result of an Embedded Floating-Point instruction.

If an Embedded Floating-Point instruction results in overflow or underflow and the corresponding Embedded Floating-Point Underflow or Embedded Floating-Point Overflow exception is disabled then the Embedded Floating-Point Round interrupt is taken.

**58 Embedded Floating-Point Invalid Operation/Input Error Exception Enable** (FINVE) [Categories: SP.FV, SPFD, SPFS]

0 Exception disabled
1 Exception enabled

If the exception is enabled, an Embedded Floating-Point Data interrupt is taken if the FINV or FINVH bit is set to 1 by an Embedded Floating-Point instruction.

**59 Embedded Floating-Point Divide By Zero Exception Enable** (FDBZE) [Categories: SP.FV, SPFD, SPFS]

0 Exception disabled
1 Exception enabled

If the exception is enabled, an Embedded Floating-Point Data interrupt is taken if the FDBZ or FDBZH bit is set to 1 by an Embedded Floating-Point instruction.

**60 Embedded Floating-Point Underflow Exception Enable** (FUNFE) [Categories: SP.FV, SPFD, SPFS]

0 Exception disabled
1 Exception enabled

If the exception is enabled, an Embedded Floating-Point Data interrupt is taken if the FUNF or FUNFH bit is set to 1 by an Embedded Floating-Point instruction.

**61 Embedded Floating-Point Overflow Exception Enable** (FOVFE) [Categories: SP.FV, SPFD, SPFS]

0 Exception disabled
1 Exception enabled

If the exception is enabled, an Embedded Floating-Point Data interrupt is taken if the FOVF or FOVFH bit is set to 1 by an Embedded Floating-Point instruction.

**62:63 Embedded Floating-Point Rounding Mode Control** (FRMC) [Categories: SP.FV, SPFD, SPFS]

00 Round to Nearest
Programming Note

Rounding modes 0b10 (+Infinity) and 0b11 (-Infinity) may not be supported by some implementations. If an implementation does not support these, Embedded Floating-Point Round interrupts are generated for every Embedded Floating-Point instruction for which rounding is required when +Infinity or -Infinity modes are set and software is required to produce the correctly rounded result.

8.3.5 Data Formats

The SPE provides two different data formats, integer and fractional. Both data formats can be treated as signed or unsigned quantities.

8.3.5.1 Integer Format

Unsigned integers consist of 16, 32, or 64-bit binary integer values. The largest representable value is $2^{n-1}$ where \( n \) represents the number of bits in the value. The smallest representable value is 0. Computations that produce values larger than $2^{n-1}$ or smaller than 0 may set OV or OVH in the SPEFSCR.

Signed integers consist of 16, 32, or 64-bit binary values in two's-complement form. The largest representable value is $2^{n-1}-1$ where \( n \) represents the number of bits in the value. The smallest representable value is $-2^{n-1}$. Computations that produce values larger than $2^{n-1}-1$ or smaller than $-2^{n-1}$ may set OV or OVH in the SPEFSCR.

8.3.5.2 Fractional Format

Fractional data format is conventionally used for DSP fractional arithmetic. Fractional data is useful for representing data converted from analog devices.

Unsigned fractions consist of 16, 32, or 64-bit binary fractional values that range from 0 to less than 1. Unsigned fractions place the radix point immediately to the left of the most significant bit. The most significant bit of the value represents the value $2^{-1}$, the next most significant bit represents the value $2^{-2}$ and so on. The largest representable value is $1-2^{-32}$ where \( n \) represents the number of bits in the value. The smallest representable value is 0. Computations that produce values larger than $1-2^{-n}$ or smaller than 0 may set OV or OVH in the SPEFSCR. The SPE category does not define unsigned fractional forms of instructions to manipulate unsigned fractional data since the unsigned integer forms of the instructions produce the same results as would the unsigned fractional forms.

Guarded unsigned fractions are 64-bit binary fractional values. Guarded unsigned fractions place the decimal point immediately to the left of bit 32. The largest representable value is $2^{32}-2^{-32}$. The smallest representable value is 0. Guarded unsigned fractional computations are always modulo and do not set OV or OVH in the SPEFSCR.

Signed fractions consist of 16, 32, or 64-bit binary fractional values in two's-complement form that range from -1 to less than 1. Signed fractions place the decimal point immediately to the right of the most significant bit. The largest representable value is $1-2^{-32+n-1}$ where \( n \) represents the number of bits in the value. The smallest representable value is -1. Computations that produce values larger than $1-2^{-32+n-1}$ or smaller than -1 may set OV or OVH in the SPEFSCR. Multiplication of two signed fractional values causes the result to be shifted left one bit to remove the resultant redundant sign bit in the product. In this case, a 0 bit is concatenated as the least significant bit of the shifted result.

Guarded signed fractions are 64-bit binary fractional values. Guarded signed fractions place the decimal point immediately to the left of bit 33. The largest representable value is $2^{32}-2^{-32}$. The smallest representable value is $-2^{-32+1}$. Guarded signed fractional computations are always modulo and do not set OV or OVH in the SPEFSCR.

8.3.6 Computational Operations

The SPE category supports several different computational capabilities. Both modulo and saturation results can be performed. Modulo results produce truncation of the overflow bits in a calculation, therefore overflow does not occur and no saturation is performed. For instructions for which overflow occurs, saturation provides a maximum or minimum representable value (for the data type) in the case of overflow. Instructions are provided for a wide range of computational capability. The operation types can be divided into 4 basic categories:

- **Simple Vector** instructions. These instructions use the corresponding low and high word elements of the operands to produce a vector result that is placed in the destination register, the accumulator, or both.

- **Multiply and Accumulate** instructions. These instructions perform multiply operations, optionally add the result to the accumulator, and place the result into the destination register and optionally into the accumulator. These instructions are composed of different multiply forms, data formats and data accumulate options. The mnemonics for these instructions indicate their various characteristics. These are shown in Table 114.

- **Load** and **Store** instructions. These instructions provide load and store capabilities for moving data...
to and from memory. A variety of forms are provided that position data for efficient computation.

- Compare and miscellaneous instructions. These instructions perform miscellaneous functions such as field manipulation, bit reversed incrementing, and vector compares.

8.3.7 SPE Instructions

8.3.8 Saturation, Shift, and Bit
Reverse Models

For saturation, left shifts, and bit reversal, the pseudo
RTL is provided here to more accurately describe those
functions that are referenced in the instruction pseudo
RTL.

8.3.8.1 Saturation

SATURATE(ov, carry, sat_ovn, sat_ov, val)
if ov then
    if carry then
        return sat_ovn
    else
        return sat_ov
else
    return val

8.3.8.2 Shift Left

SL(value, cnt)
if cnt > 31 then
    return 0
else
    return (value << cnt)

8.3.8.3 Bit Reverse

BITREVERSE(value)
result ← 0
mask ← 1
shift ← 31
cnt ← 32
while cnt > 0 then do
t ← value & mask
if shift >= 0 then
    result ← (t << shift) | result
else
    result ← (t >> -shift) | result
    cnt ← cnt - 1
    shift ← shift - 2
    mask ← mask << 1
return result
### 8.3.9 SPE Instruction Set

#### Bit Reversed Increment \( EVX\)-form

<table>
<thead>
<tr>
<th>brinc</th>
<th>RT,RA,RB</th>
</tr>
</thead>
<tbody>
<tr>
<td>(4)</td>
<td>(5)</td>
</tr>
</tbody>
</table>

\(n \leftarrow \text{implementation-dependent number of mask bits}\)

\(\text{mask} \leftarrow (\text{RB})_{64-0:63}\)

\(a \leftarrow ([\text{RA}]_{64-0:63})\)

\(d \leftarrow \text{BITREVERSE}(1 + \text{BITREVERSE}(a \mid (\neg \text{mask})))\)

\(\text{RT} \leftarrow (\text{RA})_{0:63-n} \mid (d \& \text{mask})\)

**brinc** computes a bit-reverse index based on the contents of RA and a mask specified in RB. The new index is written to RT.

The number of bits in the mask is implementation-dependent but may not exceed 32.

**Special Registers Altered:**

None

---

#### Programming Note

**brinc** provides a way for software to access FFT data in a bit-reversed manner. RA contains the index into a buffer that contains data on which FFT is to be performed. RB contains a mask that allows the index to be updated with bit-reversed addressing. Typically this instruction precedes a load with index instruction; for example,

```
brinc r2, r3, r4
lhax r8, r5, r2
```

RB contains a bit-mask that is based on the number of points in an FFT. To access a buffer containing \(n\) byte sized data that is to be accessed with bit-reversed addressing, the mask has \(\log_2 n\) 1s in the least significant bit positions and 0s in the remaining most significant bit positions. If, however, the data size is a multiple of a halfword or a word, the mask is constructed so that the 1s are shifted left by \(\log_2 (\text{size of the data})\) and 0s are placed in the least significant bit positions.

---

#### Vector Absolute Value \( EVX\)-form

<table>
<thead>
<tr>
<th>evabs</th>
<th>RT,RA</th>
</tr>
</thead>
<tbody>
<tr>
<td>(4)</td>
<td>(5)</td>
</tr>
</tbody>
</table>

\(RT_{0:31} \leftarrow \text{ABS}((\text{RA})_{0:31})\)

\(RT_{32:63} \leftarrow \text{ABS}((\text{RA})_{32:63})\)

The absolute value of each element of RA is placed in the corresponding elements of RT. An absolute value of 0x8000_0000 (most negative number) returns 0x8000_0000.

**Special Registers Altered:**

None

---

#### Vector Add Immediate Word \( EVX\)-form

<table>
<thead>
<tr>
<th>evaddiw</th>
<th>RT,RB,UI</th>
</tr>
</thead>
<tbody>
<tr>
<td>(4)</td>
<td>(5)</td>
</tr>
</tbody>
</table>

\(RT_{0:31} \leftarrow (\text{RB})_{0:31} \oplus \text{EXTZ}(\text{UI})\)

\(RT_{32:63} \leftarrow (\text{RB})_{32:63} \oplus \text{EXTZ}(\text{UI})\)

UI is zero-extended and added to both the high and low elements of RB and the results are placed in RT. Note that the same value is added to both elements of the register.

**Special Registers Altered:**

None

---

#### Vector Add Signed, Modulo, Integer to Accumulator Word \( EVX\)-form

<table>
<thead>
<tr>
<th>evaddsmiaaw</th>
<th>RT,RA</th>
</tr>
</thead>
<tbody>
<tr>
<td>(4)</td>
<td>(5)</td>
</tr>
</tbody>
</table>

\(RT_{0:31} \leftarrow (\text{ACC})_{0:31} + (\text{RA})_{0:31}\)

\(RT_{32:63} \leftarrow (\text{ACC})_{32:63} + (\text{RA})_{32:63}\)

\(\text{ACC}_{0:63} \leftarrow (\text{RT})_{0:63}\)

Each word element in RA is added to the corresponding element in the accumulator and the results are placed in RT and into the accumulator.

**Special Registers Altered:**

\(\text{ACC}\)
Vector Add Signed, Saturate, Integer to Accumulator Word EVX-form

\[\text{evaddssiaaw RT,RA}\]

\[
\begin{array}{cccccccc}
4 & RT & RA & /// & 1217 & \text{acc} & \text{ov} & \text{ovh} \\\n\end{array}
\]

\[
temp_{0:63} \leftarrow \text{EXTS}((\text{ACC})_{0:31}) + \text{EXTS}((\text{RA})_{0:31}) \]
\[
\text{ovh} \leftarrow \text{temp}_{0:31} \oplus \text{temp}_{32} \\
\text{RT}_{0:31} \leftarrow \text{SATURATE} \left(\text{ovh}, \text{temp}_{31}, 0x8000_0000, 0x7FFF_FFFF, \text{temp}_{32:63})
\]
\[
temp_{0:63} \leftarrow \text{EXTS}((\text{ACC})_{32:63}) + \text{EXTS}((\text{RA})_{32:63}) \]
\[
\text{ovl} \leftarrow \text{temp}_{31} \oplus \text{temp}_{32} \\
\text{RT}_{32:63} \leftarrow \text{SATURATE} \left(\text{ovl}, \text{temp}_{31}, 0x8000_0000, 0x7FFF_FFFF, \text{temp}_{32:63})
\]

\[\text{ACC}_{0:63} \leftarrow (\text{RT})_{0:63} \]
\[\text{SPEFSCR_{OVH}} \leftarrow \text{ovh} \]
\[\text{SPEFSCR_{OV}} \leftarrow \text{ovl} \]
\[\text{SPEFSCR_{SOVH}} \leftarrow \text{SPEFSCR_{SOVH}} | \text{ovh} \]
\[\text{SPEFSCR_{SOV}} \leftarrow \text{SPEFSCR_{SOV}} | \text{ovl} \]

Each signed-integer word element in RA is sign-extended and added to the corresponding sign-extended element in the accumulator saturating if overflow occurs, and the results are placed in RT and the accumulator.

Special Registers Altered:
- ACC
- OV
- OVH
- SOV
- SOVH

Vector Add Unsigned, Saturate, Integer to Accumulator Word EVX-form

\[\text{evaddusiaaw RT,RA}\]

\[
\begin{array}{cccccccc}
4 & RT & RA & /// & 1216 & \text{acc} & \text{ov} & \text{ovh} \\\n\end{array}
\]

\[
temp_{0:63} \leftarrow \text{EXTZ}((\text{ACC})_{0:31}) + \text{EXTZ}((\text{RA})_{0:31}) \]
\[
\text{ovh} \leftarrow \text{temp}_{0:31} \oplus \text{temp}_{31} \\
\text{RT}_{0:31} \leftarrow \text{SATURATE} \left(\text{ovh}, \text{temp}_{31}, 0xFFFF_FFFF, 0xFFFF_FFFF, \text{temp}_{32:63})
\]
\[
temp_{0:63} \leftarrow \text{EXTZ}((\text{ACC})_{32:63}) + \text{EXTZ}((\text{RA})_{32:63}) \]
\[
\text{ovl} \leftarrow \text{temp}_{31} \oplus \text{temp}_{32} \\
\text{RT}_{32:63} \leftarrow \text{SATURATE} \left(\text{ovl}, \text{temp}_{31}, 0xFFFF_FFFF, 0xFFFF_FFFF, \text{temp}_{32:63})
\]

\[\text{ACC}_{0:63} \leftarrow (\text{RT})_{0:63} \]
\[\text{SPEFSCR_{OVH}} \leftarrow \text{ovh} \]
\[\text{SPEFSCR_{OV}} \leftarrow \text{ovl} \]
\[\text{SPEFSCR_{SOVH}} \leftarrow \text{SPEFSCR_{SOVH}} | \text{ovh} \]
\[\text{SPEFSCR_{SOV}} \leftarrow \text{SPEFSCR_{SOV}} | \text{ovl} \]

Each unsigned-integer word element in RA is zero-extended and added to the corresponding zero-extended element in the accumulator saturating if overflow occurs, and the results are placed in RT and the accumulator.

Special Registers Altered:
- ACC
- OV
- OVH
- SOV
- SOVH

Vector Add Unsigned, Modulo, Integer to Accumulator Word EVX-form

\[\text{evaddumiaaw RT,RA}\]

\[
\begin{array}{cccccccc}
4 & RT & RA & /// & 1224 & \text{acc} & \text{ov} \\\n\end{array}
\]

\[
\text{RT}_{0:31} \leftarrow (\text{ACC})_{0:31} + (\text{RA})_{0:31} \\
\text{RT}_{32:63} \leftarrow (\text{ACC})_{32:63} + (\text{RA})_{32:63} \\
\text{ACC}_{0:63} \leftarrow (\text{RT})_{0:63}
\]

Each unsigned-integer word element in RA is added to the corresponding element in the accumulator and the results are placed in RT and the accumulator.

Special Registers Altered:
- ACC

Vector Add Word EVX-form

\[\text{evadw RT,RA,RB}\]

\[
\begin{array}{cccccccc}
4 & RT & RA & RB & /// & 512 & \text{acc} & \text{ov} \\\n\end{array}
\]

\[
\text{RT}_{0:31} \leftarrow (\text{RA})_{0:31} + (\text{RB})_{0:31} \\
\text{RT}_{32:63} \leftarrow (\text{RA})_{32:63} + (\text{RB})_{32:63}
\]

The corresponding elements of RA and RB are added and the results are placed in RT. The sum is a modulo sum.

Special Registers Altered:
- None
Vector AND

```
evand RT,RA,RB
```

```
<table>
<thead>
<tr>
<th></th>
<th>4</th>
<th>RT</th>
<th>RA</th>
<th>RB</th>
<th>529</th>
</tr>
</thead>
<tbody>
<tr>
<td>p</td>
<td></td>
<td>i1</td>
<td>h6</td>
<td>i1</td>
<td></td>
</tr>
</tbody>
</table>

```

\[
\begin{align*}
RT_{0:31} & \leftarrow [RA]_{0:31} \land [RB]_{0:31} \\
RT_{32:63} & \leftarrow [RA]_{32:63} \land [RB]_{32:63}
\end{align*}
\]

The corresponding elements of RA and RB are ANDed bitwise and the results are placed in the corresponding element of RT.

Special Registers Altered:
None

Vector AND with Complement

```
evandc RT,RA,RB
```

```
<table>
<thead>
<tr>
<th></th>
<th>4</th>
<th>RT</th>
<th>RA</th>
<th>RB</th>
<th>530</th>
</tr>
</thead>
<tbody>
<tr>
<td>p</td>
<td></td>
<td>i1</td>
<td>h6</td>
<td>i1</td>
<td></td>
</tr>
</tbody>
</table>

```

```
\[
\begin{align*}
RT_{0:31} & \leftarrow (RA)_{0:31} \land \neg (RB)_{0:31} \\
RT_{32:63} & \leftarrow (RA)_{32:63} \land \neg (RB)_{32:63}
\end{align*}
\]

The word elements of RA are ANDed bitwise with the complement of the corresponding elements of RB. The results are placed in the corresponding element of RT.

Special Registers Altered:
None

Vector Compare Equal

```
evcmp eq BF,RA,RB
```

```
<table>
<thead>
<tr>
<th></th>
<th>4</th>
<th>BF</th>
<th>//</th>
<th>RA</th>
<th>RB</th>
<th>564</th>
</tr>
</thead>
<tbody>
<tr>
<td>p</td>
<td></td>
<td>b6</td>
<td>h6</td>
<td>i1</td>
<td>i1</td>
<td></td>
</tr>
</tbody>
</table>

```

```
\[
\begin{align*}
ah & \leftarrow [RA]_{0:31} \\
al & \leftarrow [RA]_{32:63} \\
bh & \leftarrow [RB]_{0:31} \\
bl & \leftarrow [RB]_{32:63} \\
\text{if}\ (ah = bh) & \text{then} \ ch \leftarrow 1 \\
\text{else} \ ch \leftarrow 0 \\
\text{if}\ (al = bl) & \text{then} \ cl \leftarrow 1 \\
\text{else} \ cl \leftarrow 0 \\
\end{align*}
\]

\[
\text{CR}4_{4\times BF+32;4\times BF+35} \leftarrow \text{ch} || \text{cl} || \text{(ch} \land \text{cl)} || \text{(ch} \lor \text{cl)}
\]

The most significant bit in BF is set if the high-order element of RA is equal to the high-order element of RB; it is cleared otherwise. The next bit in BF is set if the low-order element of RA is equal to the low-order element of RB and cleared otherwise. The last two bits of BF are set to the OR and AND of the result of the compare of the high and low elements.

Special Registers Altered:
CR field BF

Vector Compare Greater Than Signed

```
evcmp gts BF,RA,RB
```

```
<table>
<thead>
<tr>
<th></th>
<th>4</th>
<th>BF</th>
<th>//</th>
<th>RA</th>
<th>RB</th>
<th>561</th>
</tr>
</thead>
<tbody>
<tr>

    RT32:63 ← 0xFFFFFFFF
    ovl ← 1
SPEFSCROVH ← ovh
SPEFSCROV ← ovl
SPEFSCRSOVH ← SPEFSCRSOVH | ovh
SPEFSCRSOV ← SPEFSCRSOV | ovl

The two dividends are the two elements of the contents of RA. The two divisors are the two elements of the contents of RB. Two 32-bit quotients are formed as a result of the division on each of the high and low elements and the quotients are placed into RT. Rema

Special Registers Altered:
OV OVH SOV SOVH

Programming Note
Note that any overflow indication is always set as a side effect of this instruction. No form is defined that disables the setting of the overflow bits. In case of overflow, a saturated value is delivered into the destination register.

Vector Equivalent

Vector Equivalent

\[
eveqv \quad RT, RA, RB
\]

\[
\begin{array}{c|c|c|c|c|c|c|c}
4 & RT & RA & RB & 537 & 31
\end{array}
\]

RT0:31 ← (RA)0:31 = (RB)0:31
RT32:63 ← (RA)32:63 = (RB)32:63

The corresponding elements of RA and RB are XORed bitwise, and the complemented results are placed in RT.

Special Registers Altered:
None

Vector Extend Sign Byte

Vector Extend Sign Byte

\[
evextsb \quad RT, RA
\]

\[
\begin{array}{c|c|c|c|c|c|c|c}

\( RT_{32:63} \leftarrow (RB)_{32:63} \)

The low-order elements of \( RA \) and \( RB \) are merged and placed in \( RT \).

Special Registers Altered:
None

---

**Programming Note**

A vector splat high can be performed by specifying the same register in \( RA \) and \( RB \).

---

A vector splat low can be performed by specifying the same register in \( RA \) and \( RB \).
Vector Merge High/Low EVX-form

evmergehilo RT,RA,RB

| 4 | RT | RA | RB | 558 |

RT0:31 ← (RA)0:31
RT32:63 ← (RB)32:63

The high-order element of RA and the low-order element of RB are merged and placed in RT.

Special Registers Altered:
None

Programming Note
With appropriate specification of RA and RB, evmergehi, evmergelohi, evmergehilo, and evmergelohi provide a full 32-bit permute of two source operands.

Vector Multiply Halfwords, Even, Guarded, Signed, Modulo, Fractional and Accumulate EVX-form

evmsmfaa RT,RA,RB

| 4 | RT | RA | RB | 1323 |

temp0:63 ← (RA)32:47 × gsf (RB)32:47
RT0:63 ← (ACC)0:63 + temp0:63
ACC0:63 ← (RT)0:63

The corresponding low even-numbered, halfword signed fractional elements in RA and RB are multiplied using guarded signed fractional multiplication producing a sign extended 64-bit fractional product with the decimal between bits 32 and 33. The product is added to the contents of the 64-bit accumulator and the result is placed in RT and the accumulator.

Special Registers Altered:
ACC

Note
If the two input operands are both -1.0, the intermediate product is represented as +1.0.

Vector Merge Low/High EVX-form

evmergelohi RT,RA,RB

| 4 | RT | RA | RB | 559 |

RT0:31 ← (RA)32:63
RT32:63 ← (RB)0:31

The low-order element of RA and the high-order element of RB are merged and placed in RT.

Special Registers Altered:
None

Programming Note
A vector swap can be performed by specifying the same register in RA and RB.

Vector Multiply Halfwords, Even, Guarded, Signed, Modulo, Fractional and Accumulate Negative EVX-form

evmsmfan RT,RA,RB

| 4 | RT | RA | RB | 1451 |

temp0:63 ← (RA)32:47 × gsf (RB)32:47
RT0:63 ← (ACC)0:63 - temp0:63
ACC0:63 ← (RT)0:63

The corresponding low even-numbered, halfword signed fractional elements in RA and RB are multiplied using guarded signed fractional multiplication producing a sign extended 64-bit fractional product with the decimal between bits 32 and 33. The product is subtracted from the contents of the 64-bit accumulator and the result is placed in RT and the accumulator.

Special Registers Altered:
ACC

Note
If the two input operands are both -1.0, the intermediate product is represented as +1.0.
Vector Multiply Halfwords, Even, Guarded, Signed, Modulo, Integer and Accumulate EVX-form

Each element of RA and RB is bitwise NANDed. The result is placed in the corresponding element of RT.

**Special Registers Altered:**

None

**Vector Negate** EVX-form

evneg RT,RA

<table>
<thead>
<tr>
<th>4</th>
<th>RT</th>
<th>RA</th>
<th>521</th>
</tr>
</thead>
</table>

| RT0:31 | $\text{NEG} \left( \left[ \text{RA} \right]_{0:31} \right)$ |
| RT32:63 | $\text{NEG} \left( \left[ \text{RA} \right]_{32:63} \right)$ |

The negative of each element of RA is placed in RT. The negative of 0x8000_0000 (most negative number) returns 0x8000_0000.

**Special Registers Altered:**

None
### Vector NOR

**EVX-form**

```
evnor RT,RA,RB
```

<table>
<thead>
<tr>
<th>0</th>
<th>1</th>
<th>31</th>
<th>32</th>
<th>33</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>5</td>
<td>11</td>
<td>16</td>
<td>31</td>
</tr>
</tbody>
</table>

\[
\begin{align*}
RT_{0:31} & \leftarrow \neg ((RA)_{0:31} \mid (RB)_{0:31}) \\
RT_{32:63} & \leftarrow \neg ((RA)_{32:63} \mid (RB)_{32:63})
\end{align*}
\]

Each element of RA and RB is bitwise NORed. The result is placed in the corresponding element of RT.

**Special Registers Altered:** None

**Extended Mnemonics:**

Extended mnemonics are provided for the Vector NOR instruction to produce a vector bitwise complement operation.

**Extended:** Equivalent to:

```
evnot RT,RA
evnor RT,RA,RA
```

### Vector OR

**EVX-form**

```
evor RT,RA,RB
```

<table>
<thead>
<tr>
<th>0</th>
<th>1</th>
<th>31</th>
<th>32</th>
<th>33</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>5</td>
<td>11</td>
<td>16</td>
<td>31</td>
</tr>
</tbody>
</table>

\[
\begin{align*}
RT_{0:31} & \leftarrow (RA)_{0:31} \mid (RB)_{0:31} \\
RT_{32:63} & \leftarrow (RA)_{32:63} \mid (RB)_{32:63}
\end{align*}
\]

Each element of RA and RB is bitwise ORed. The result is placed in the corresponding element of RT.

**Special Registers Altered:** None

**Extended Mnemonics:**

Extended mnemonics are provided for the Vector OR instruction to provide a 64-bit vector move instruction.

**Extended:** Equivalent to:

```
evmr RT,RA
evor RT,RA,RA
```

### Vector OR with Complement

**EVX-form**

```
evorc RT,RA,RB
```

<table>
<thead>
<tr>
<th>0</th>
<th>1</th>
<th>31</th>
<th>32</th>
<th>33</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>5</td>
<td>11</td>
<td>16</td>
<td>31</td>
</tr>
</tbody>
</table>

\[
\begin{align*}
RT_{0:31} & \leftarrow (RA)_{0:31} \mid \neg (RB)_{0:31} \\
RT_{32:63} & \leftarrow (RA)_{32:63} \mid \neg (RB)_{32:63}
\end{align*}
\]

Each element of RA is bitwise ORed with the complement of RB. The result is placed in the corresponding element of RT.

**Special Registers Altered:** None

### Vector Rotate Left Word

**EVX-form**

```
evrlw RT,RA,RB
```

<table>
<thead>
<tr>
<th>0</th>
<th>1</th>
<th>31</th>
<th>32</th>
<th>33</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>5</td>
<td>11</td>
<td>16</td>
<td>31</td>
</tr>
</tbody>
</table>

\[
\begin{align*}
\text{nh} & \leftarrow (RB)_{27:31} \\
\text{nl} & \leftarrow (RB)_{59:63} \\
RT_{0:31} & \leftarrow \text{ROTL}((RA)_{0:31}, \text{nh}) \\
RT_{32:63} & \leftarrow \text{ROTL}((RA)_{32:63}, \text{nl})
\end{align*}
\]

Each of the high and low elements of RA is rotated left by an amount specified in RB. The result is placed in RT. Rotate values for each element of RA are found in bit positions RB_{27:31} and RB_{59:63}.

**Special Registers Altered:** None
**Vector Rotate Left Word Immediate**

*EVX-form*

```
evrwi    RT,RA,UI
```

$$\begin{array}{cc}
\text{4} & \text{RT} & \text{RA} & \text{UI} & \text{554} \\
\end{array}$$

\[n \leftarrow \text{UI}\]
\[\text{RT}_{0:31} \leftarrow \text{ROTL}((\text{RA})_{0:31}, n)\]
\[\text{RT}_{32:63} \leftarrow \text{ROTL}((\text{RA})_{32:63}, n)\]

Both the high and low elements of RA are rotated left by an amount specified by UI.

**Special Registers Altered:**

None

---

**Vector Round Word**

*EVX-form*

```
evrdw    RT,RA
```

$$\begin{array}{cc}
\text{4} & \text{RT} & \text{RA} & /// & \text{524} \\
\end{array}$$

\[\text{RT}_{0:31} \leftarrow ((\text{RA})_{0:31} + 0x00008000) \& 0xFFFF0000\]
\[\text{RT}_{32:63} \leftarrow ((\text{RA})_{32:63} + 0x00008000) \& 0xFFFF0000\]

The 32-bit elements of RA are rounded into 16 bits. The result is placed in RT. The resulting 16 bits are placed in the most significant 16 bits of each element of RT, zeroing out the low-order 16 bits of each element.

**Special Registers Altered:**

None

---

**Vector Select**

*EVS-form*

```
evsel    RT,RA,RB,BFA
```

$$\begin{array}{cc}
\text{4} & \text{RT} & \text{RA} & \text{RB} & \text{BFA} & \text{79} \\
\end{array}$$

\[\text{ch} \leftarrow \text{CR}_{\text{BFA}\_4}\]
\[\text{cl} \leftarrow \text{CR}_{\text{BFA}\_4+1}\]

if (ch = 1) then
\[\text{RT}_{0:31} \leftarrow (\text{RA})_{0:31}\]
else
\[\text{RT}_{0:31} \leftarrow (\text{RB})_{0:31}\]

if (cl = 1) then
\[\text{RT}_{32:63} \leftarrow (\text{RA})_{32:63}\]
else
\[\text{RT}_{32:63} \leftarrow (\text{RB})_{32:63}\]

If the most significant bit in the BFA field of CR is set to 1, the high-order element of RA is placed in the high-order element of RT; otherwise, the high-order element of RB is placed into the high-order element of RT. If the next most significant bit in the BFA field of CR is set to 1, the low-order element of RA is placed in the low-order element of RT, otherwise, the low-order element of RB is placed into the low-order element of RT.

**Special Registers Altered:**

None
Vector Shift Left Word

**EVX-form**

```
evslw RT, RA, RB
```

<table>
<thead>
<tr>
<th>p</th>
<th>RT</th>
<th>RA</th>
<th>RB</th>
<th>548</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>5</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

\[ \text{nh} \leftarrow (RB)_{26:31} \]
\[ \text{nl} \leftarrow (RB)_{58:63} \]
\[ RT_{0:31} \leftarrow \text{SL}((RA)_{0:31}, \text{nh}) \]
\[ RT_{32:63} \leftarrow \text{SL}((RA)_{32:63}, \text{nl}) \]

Each of the high and low elements of RA is shifted left by an amount specified in RB. The result is placed in RT. The separate shift amounts for each element are specified by 6 bits in RB that lie in bit positions 26:31 and 58:63.

Shift amounts from 32 to 63 give a zero result.

**Special Registers Altered:**

None

Vector Shift Left Word Immediate

**EVX-form**

```
evslwi RT, RA, UI
```

<table>
<thead>
<tr>
<th>p</th>
<th>RT</th>
<th>RA</th>
<th>UI</th>

Chapter 9. Embedded Floating-Point
[Category: SPE.Embedded Float Scalar Double]
[Category: SPE.Embedded Float Scalar Single]
[Category: SPE.Embedded Float Vector]

9.1 Overview

The Embedded Floating-Point categories require the implementation of the Signal Processing Engine (SPE) category and consist of three distinct categories:

- Embedded vector single-precision floating-point (SPE.Embedded Float Vector [SP.FV])
- Embedded scalar single-precision floating-point (SPE.Embedded Float Scalar Single [SP.FS])
- Embedded scalar double-precision floating-point (SPE.Embedded Float Scalar Double [SP.FD])

Although each of these may be implemented independently, they are defined in a single chapter because it is likely that they may be implemented together.

References to Embedded Floating-Point categories, Embedded Floating-Point instructions, or Embedded Floating-Point operations apply to all 3 categories.

Single-precision floating-point is handled by the SPE.Embedded Float Vector and SPE.Embedded Float Scalar Single categories; double-precision floating-point is handled by the SPE.Embedded Float Scalar Double category.
9.2 Programming Model

Embedded floating-point operations are performed in the GPRs of the processor.

The SPE.Embedded Float Vector and SPE.Embedded Float Scalar Double categories require a GPR register file with thirty-two 64-bit registers as required by the Signal Processing Engine category.

The SPE.Embedded Float Scalar Single category requires a GPR register file with thirty-two 32-bit registers. When implemented with a 64-bit register file on a 32-bit implementation, instructions in this category only use and modify bits 32:63 of the GPR. In this case, bits 0:31 of the GPR are left unchanged by the operation. For 64-bit implementations, bits 0:31 are unchanged after the operation.

Instructions in the SPE.Embedded Float Scalar Double category operate on the entire 64 bits of the GPRs.

Instructions in the SPE.Embedded Float Vector category operate on the entire 64 bits of the GPRs as well, but contain two 32-bit data items that are operated on independently of each other in a SIMD fashion. The format of both data items is the same as the format of a data item in the SPE.Embedded Float Scalar Single category. The data item contained in bits 0:31 is called the 'high word'. The data item contained in bits 32:63 is called the 'low word'.

There are no record forms of Embedded Floating-Point instructions. Embedded Floating-Point Compare instructions treat NaNs, Infinity, and Denorm as normalized numbers for the comparison calculation when default results are provided.

9.2.1 Signal Processing Embedded Floating-Point Status and Control Register (SPEFSCR)

Status and control for the Embedded Floating-Point categories uses the SPEFSCR. This register is defined by the Signal Processing Engine category in Section 8.3.4. Status and control bits are shared for Embedded Floating-Point and SPE operations. Instructions in the SPE.Embedded Float Vector category affect both the high element (bits 34:39) and low element floating-point status flags (bits 50:55). Instructions in the SPE.Embedded Float Scalar Double and SPE.Embedded Float Scalar Single categories affect only the low element floating-point status flags and leave the high element floating-point status flags undefined.

9.2.2 Floating-Point Data Formats

Single-precision floating-point data elements are 32 bits wide with 1 sign bit (s), 8 bits of biased exponent (e) and 23 bits of fraction (f). Double-precision floating-point data elements are 64 bits wide with 1 sign bit (s), 11 bits of biased exponent (e) and 52 bits of fraction (f).

In the IEEE 754 specification, floating-point values are represented in a format consisting of three explicit fields (sign field, biased exponent field, and fraction field) and an implicit hidden bit.

![Figure 130. Floating-Point Data Format](image)

For single-precision normalized numbers, the biased exponent value e lies in the range of 1 to 254 corresponding to an actual exponent value E in the range -126 to +127. For double-precision normalized numbers, the biased exponent value e lies in the range of 1 to 2046 corresponding to an actual exponent value E in the range -1022 to +1023. With the hidden bit implied to be '1' (for normalized numbers), the value of the number is interpreted as follows:

\[ (-1)^s \times 2^e \times (1.fraction) \]

where E is the unbiased exponent and 1.fraction is the mantissa (or significand) consisting of a leading '1' (the hidden bit) and a fractional part (fraction field). For the single-precision format, the maximum positive normalized number (pmax) is represented by the encoding 0x7F7FFFFF which is approximately 3.4E+38 (2^{128}), and the minimum positive normalized value (pmin) is represented by the encoding 0x00800000 which is approximately 1.2E-38 (2^{-126}). For the double-precision format, the maximum positive normalized number (pmax) is represented by the encoding 0x7fecccccccccccccccc which is approximately 7.1E+307 (2^{1024}), and the minimum positive normalized value (pmin) is represented by the encoding 0x0010000000000000 which is approximately 2.2E-308 (2^{-1022}).

Two specific values of the biased exponent are reserved (0 and 255 for single-precision; 0 and 2047 for double-precision) for encoding special values of +0, -0, +infinity, -infinity, and NaNs.

Zeros of both positive and negative sign are represented by a biased exponent value e of 0 and a fraction f which is 0.

Infinites of both positive and negative sign are represented by a maximum exponent field value (255 for single-precision, 2047 for double-precision) and a fraction which is 0.
Denormalized numbers of both positive and negative sign are represented by a biased exponent value \( e \) of 0 and a fraction \( f \), which is nonzero. For these numbers, the hidden bit is defined by the IEEE 754 standard to be 0. This number type is not directly supported in hardware. Instead, either a software interrupt handler is invoked, or a default value is defined.

Not-a-Numbers (NaNs) are represented by a maximum exponent field value (255 for single-precision, 2047 for double-precision) and a fraction \( f \), which is nonzero. For these numbers, the hidden bit is defined by the IEEE 754 standard to be 0. This number type is not directly supported in hardware. Instead, either a software interrupt handler is invoked, or a default value is defined.

9.2.3 Exception Conditions

9.2.3.1 Denormalized Values on Input
Any denormalized value used as an operand may be truncated by the implementation to a properly signed zero value.

9.2.3.2 Embedded Floating-Point Overflow and Underflow
Defining \( p_{max} \) to be the most positive normalized value (farthest from zero), \( p_{min} \) the smallest positive normalized value (farthest from zero) and \( n_{max} \) the smallest normalized negative value (closest to zero), an overflow is said to have occurred if the numerically correct result \( r \) of an instruction is such that \( r > p_{max} \) or \( r < n_{max} \). An underflow is said to have occurred if the numerically correct result of an instruction is such that \( 0 < r < p_{min} \) or \( n_{min} < r < 0 \). In this case, \( r \) may be denormalized, or may be smaller than the smallest denormalized number.

The Embedded Floating-Point categories do not produce +Infinity, -Infinity, NaN, or denormalized numbers. If the result of an instruction overflows and Embedded Floating-Point Overflow exceptions are disabled (SPEFSCR\_FVFE=0), \( p_{max} \) or \( n_{max} \) is generated as the result of that instruction depending upon the sign of the result. If the result of an instruction underflows and Embedded Floating-Point Underflow exceptions are disabled (SPEFSCR\_FUNE=0), +0 or -0 is generated as the result of that instruction based upon the sign of the result.

If an overflow occurs, SPEFSCR\_FOVF FOVFH are set as appropriate, or if an underflow occurs, SPEFSCR\_FUNF FUNFH are set as appropriate. If either Embedded Floating-Point Underflow or Embedded Floating-Point Overflow exceptions are enabled and a corresponding status bit is 1, an Embedded Floating-Point Data interrupt is taken and the destination register is not updated.

9.2.3.3 Embedded Floating-Point Invalid Operation/Input Errors
Embedded Floating-Point Invalid Operation/Input errors occur when an operand to an operation contains an invalid input value. If any of the input values are Infinity, Denorm, or NaN, or for an Embedded Floating-Point Divide instruction both operands are +/-0, SPEFSCR\_F. INV\_FINVH are set to 1 appropriately, and SPEFSCR\_FXH FG FXH are set to 0 appropriately. If SPEFSCR\_F, INVE=1, an Embedded Floating-Point Data interrupt is taken and the destination register is not updated.

9.2.3.4 Embedded Floating-Point Round (Inexact)
If any result element of an Embedded Floating-Point instruction is inexact, or overflows but Embedded Floating-Point Overflow exceptions are disabled, or underflows but Embedded Floating-Point Underflow exceptions are disabled, and no higher priority interrupt occurs, SPEFSCR\_FINXS is set to 1. If the Embedded Floating-Point Round (inexact) exception is enabled, an Embedded Floating-Point Round interrupt occurs. In this case, the destination register is updated with the truncated result(s). The SPEFSCR\_FGH FXH FG FX bits are properly updated to allow rounding to be performed in the interrupt handler.

SPEFSCR\_FG FX (SPEFSCR\_FGH FXH) are set to 0 if an Embedded Floating-Point Data interrupt is taken due to overflow, underflow, or if an Embedded Floating-Point Invalid Operation/Input error is signaled for the low (high) element (regardless of SPEFSCR\_FINVE).

9.2.3.5 Embedded Floating-Point Divide by Zero
If an Embedded Floating-Point Divide instruction executes and an Embedded Floating-Point Invalid Operation/Input error does not occur and the instruction is executed with a +/-0 divisor value and a finite normalized nonzero dividend value, an Embedded Floating-Point Divide By Zero exception occurs and SPEFSCR\_FDBZ FDBZH are set appropriately. If Embedded Floating-Point Divide By Zero exceptions are enabled, an Embedded Floating-Point Data interrupt is taken and the destination register is not updated.

Programming Note
On some implementations, operations that result in overflow or underflow are likely to take significantly longer than operations that do not. For example, these operations may cause a system error handler to be invoked; on such implementations, the system error handler updates the overflow bits appropriately.
interrupt is then taken and the destination register is not updated.

9.2.3.6 Default Results

Default results are generated when an Embedded Floating-Point Invalid Operation/Input Error, Embedded Floating-Point Overflow, Embedded Floating-Point Underflow, or Embedded Floating-Point Divide by Zero occurs on an Embedded Floating-Point operation. Default results provide a normalized value as a result of the operation. In general, Denorm results and underflows are set to 0 and overflows are saturated to the maximum representable number.

Default results produced for each operation are described in Section 9.4, “Embedded Floating-Point Results Summary”.

9.2.4 IEEE 754 Compliance

The Embedded Floating-Point categories require a floating-point system as defined in the ANSI/IEEE Standard 754-1985 but may rely on software support in order to conform fully with the standard. Thus, whenever an input operand of the Embedded Floating-Point instruction has data values that are +Infinity, -Infinity, Denormalized, NaN, or when the result of an operation produces an overflow or an underflow, an Embedded Floating-Point Data interrupt may be taken and the interrupt handler is responsible for delivering IEEE 754 compliant behavior if desired.

When Embedded Floating-Point Invalid Operation/Input Error exceptions are disabled (SPEFSCRFINVE = 0), default results are produced by the hardware when an Infinity, Denormalized, or NaN input is received, or for the operation 0/0. When Embedded Floating-Point Underflow exceptions are disabled (SPEFSCRFUNFE = 0) and the result of a floating-point operation underflows, a signed zero result is produced. The Embedded Floating-Point Round (Inexact) exception is also signaled for this condition. When Embedded Floating-Point Overflow exceptions are disabled (SPEFSCRFOVFE = 0) and the result of a floating-point operation overflows, a pmax or nmax result is produced. The Embedded Floating-Point Round (Inexact) exception is also signaled for this condition. An exception enable flag (SPEFSCRFINXE) is also provided for generating an Embedded Floating-Point Round interrupt when an inexact result is produced, to allow a software handler to conform to the IEEE 754 standard. An Embedded Floating-Point Divide By Zero exception enable flag (SPEFSCRFDBZE) is provided for generating an Embedded Floating-Point Data interrupt when a divide by zero operation is attempted to allow a software handler to conform to the IEEE 754 standard. All of these exceptions may be disabled, and the hardware will then deliver an appropriate default result.

The sign of the result of an addition operation is the sign of the source operand having the larger absolute value. If both operands have the same sign, the sign of the result is the same as the sign of the operands. This includes subtraction which is addition with the negation of the sign of the second operand. The sign of the result of an addition operation with operands of differing signs for which the result is zero is positive except when rounding to negative infinity. Thus -0 + -0 = -0, and all other cases which result in a zero value give +0 unless the rounding mode is round to negative infinity.

--- Programming Note ---

Note that when exceptions are disabled and default results computed, operations having input values that are denormalized may provide different results on different implementations. An implementation may choose to use the denormalized value or a zero value for any computation. Thus a computational operation involving a denormalized value and a normal value may return different results depending on the implementation.

9.2.4.1 Sticky Bit Handling For Exception Conditions

The SPEFSCR register defines sticky bits for retaining information about exception conditions that are detected. There are 5 sticky bits (FINXS, FINVS, FDBZS, FUNFS and FOVFS) that can be used to help provide IEEE 754 compliance. The sticky bits represent the combined ‘or’ of all the previous status bits produced from any Embedded Floating-Point operation since the last time software zeroed the sticky bit. The hardware will never set a sticky bit to 0.
9.3 Embedded Floating-Point Instructions

9.3.1 Load/Store Instructions

*Embedded Floating-Point* instructions use GPRs to hold and operate on floating-point values. The *Embedded Floating-Point* categories do not define *Load* and *Store* instructions to move the data to and from memory, but instead rely on existing instructions in Book I to load and store data.

### Vector Floating-Point Single-Precision

#### Absolute Value

<table>
<thead>
<tr>
<th>Instruction</th>
<th>RT,RA</th>
</tr>
</thead>
<tbody>
<tr>
<td>evfsabs</td>
<td></td>
</tr>
</tbody>
</table>

\[
\begin{array}{cccccccc}
4 & 9 & 11 & 16 & 21 & 31 & 644 & 0 \\
\end{array}
\]

\[
RT_{0..31} \leftarrow 0b0 || (RA)_{1..31} \\
RT_{32..63} \leftarrow 0b0 || (RA)_{33..63}
\]

The sign bit of each element in register RA is set to 0 and the results are placed into register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

Special Registers Altered:

None

#### Negative Absolute Value

<table>
<thead>
<tr>
<th>Instruction</th>
<th>RT,RA</th>
</tr>
</thead>
<tbody>
<tr>
<td>evfsnabs</td>
<td></td>
</tr>
</tbody>
</table>

\[
\begin{array}{cccccccc}
4 & 9 & 11 & 16 & 21 & 31 & 645 & 0 \\
\end{array}
\]

\[
RT_{0..31} \leftarrow 0b1 || (RA)_{1..31} \\
RT_{32..63} \leftarrow 0b1 || (RA)_{33..63}
\]

The sign bit of each element in register RA is set to 1 and the results are placed into register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

Special Registers Altered:

None

#### Negate

<table>
<thead>
<tr>
<th>Instruction</th>
<th>RT,RA</th>
</tr>
</thead>
<tbody>
<tr>
<td>evfsneg</td>
<td></td>
</tr>
</tbody>
</table>

\[
\begin{array}{cccccccc}
0 & 9 & 11 & 16 & 21 & 31 & 646 & 0 \\
\end{array}
\]

\[
RT_{0..31} \leftarrow \neg (RA)_{0} || (RA)_{1..31} \\
RT_{32..63} \leftarrow \neg (RA)_{32} || (RA)_{33..63}
\]

The sign bit of each element in register RA is complemented and the results are placed into register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

Special Registers Altered:

None

9.3.2 SPE.Embedded Float Vector Instructions [Category: SPE.Embedded Float Vector]

All SPE.Embedded Float Vector instructions are single-precision. There are no vector floating-point double-precision instructions.
### Vector Floating-Point Single-Precision Add

**EVX-form**

```
<table>
<thead>
<tr>
<th></th>
<th>p</th>
<th>RT</th>
<th>RA</th>
<th>RB</th>
<th>640</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>31</td>
</tr>
</tbody>
</table>
```

```
RT_{0:31} ← (RA)_{0:31} + (RB)_{0:31}
RT_{32:63} ← (RA)_{32:63} + (RB)_{32:63}
```

Each single-precision floating-point element of register RA is added to the corresponding element of register RB and the results are stored in register RT.

If an underflow occurs, +0 (for rounding modes RN, RZ, RP) or -0 (for rounding mode RM) is stored in the corresponding element of register RT.

### Vector Floating-Point Single-Precision Divide

**EVX-form**

```
<table>
<thead>
<tr>
<th></th>
<th>p</th>
<th>RT</th>
<th>RA</th>
<th>RB</th>
<th>649</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>31</td>
</tr>
</tbody>
</table>
```

```
RT_{0:31} ← (RA)_{0:31} ÷ (RB)_{0:31}
RT_{32:63} ← (RA)_{32:63} ÷ (RB)_{32:63}
```

Each single-precision floating-point element of register RA is divided by the corresponding element of register RB and the result is stored in register RT.

**Special Registers Altered:**

- FINV
- FINVH
- FINVS
- FGH
- FXH
- FG
- FX
- FINXS
- FDBZ
- FDBZH
- FDBZS
- FOVF
- FOVFH

**Vector Floating-Point Single-Precision**  
**Compare Greater Than**  
**EVX-form**

```
evfscmpgt BF ,RA,RB
```

<table>
<thead>
<tr>
<th>4</th>
<th>BF</th>
<th>RA</th>
<th>RB</th>
<th>652</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>p</td>
<td>t1</td>
<td>t0</td>
<td></td>
</tr>
</tbody>
</table>

```
ah ← (RA)0:31
al ← (RA)32:63
bh ← (RB)0:31
bl ← (RB)32:63
if (ah > bh) then ch ← 1
else ch ← 0
if (al > bl) then cl ← 1
else cl ← 0
CR4×BF:4×BF+3 ← ch || cl || (ch | cl) || (ch & cl)
```

Each element of register RA is compared against the corresponding element of register RB. The results of the comparisons are placed into CR field BF. If RA0:31 is greater than RB0:31, bit 0 of CR field BF is set to 1, otherwise it is set to 0. If RA32:63 is greater than RB32:63, bit 1 of CR field BF is set to 1, otherwise it is set to 0. Bit 2 of CR field BF is set to the OR of both result bits and Bit 3 of CR field BF is set to the AND of both result bits. Comparison ignores the sign of 0 (+0 = -0).

If an input error occurs and default results are generated, NaNs, Infinities, and Denorms are treated as normalized numbers, using their values of ‘e’ and ‘f’ directly.

9.3.3 SPE.Embedded Float Scalar Single Instructions

[Category: SPE.Embedded Float Scalar Single]

**Floating-Point Single-Precision Absolute Value EVX-form**

<table>
<thead>
<tr>
<th>efsabs</th>
<th>RT,RA</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>RT</td>
</tr>
<tr>
<td>11</td>
<td>RA</td>
</tr>
<tr>
<td>///</td>
<td>708</td>
</tr>
</tbody>
</table>

\[ RT_{32:63} \leftarrow 0b0 || (RA)_{33:63} \]

The sign bit of the low element of register RA is set to 0 and the result is placed into the low element of register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

**Special Registers Altered:**

None

**Floating-Point Single-Precision Negative Absolute Value EVX-form**

<table>
<thead>
<tr>
<th>efsnabs</th>
<th>RT,RA</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>RT</td>
</tr>
<tr>
<td>11</td>
<td>RA</td>
</tr>
<tr>
<td>///</td>
<td>709</td>
</tr>
</tbody>
</table>

\[ RT_{32:63} \leftarrow 0b1 || (RA)_{33:63} \]

The sign bit of the low element of register RA is set to 1 and the result is placed into the low element of register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

**Special Registers Altered:**

None

**Floating-Point Single-Precision Negate EVX-form**

<table>
<thead>
<tr>
<th>efsneg</th>
<th>RT,RA</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>RT</td>
</tr>
<tr>
<td>11</td>
<td>RA</td>
</tr>
<tr>
<td>///</td>
<td>710</td>
</tr>
</tbody>
</table>

\[ RT_{32:63} \leftarrow \neg (RA)_{32} || (RA)_{33:63} \]

The sign bit of the low element of register RA is complemented and the result is placed into the low element of register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

**Special Registers Altered:**

None
### Floating-Point Single-Precision Add

**EVX-form**

<table>
<thead>
<tr>
<th>efsadd</th>
<th>RT, RA, RB</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>8</td>
</tr>
<tr>
<td>p</td>
<td>f1</td>
</tr>
<tr>
<td>32:63</td>
<td>704</td>
</tr>
</tbody>
</table>

\[ RT_{32:63} \leftarrow (RA)_{32:63} + sp (RB)_{32:63} \]

The low element of register RA is added to the low element of register RB and the result is stored in the low element of register RT.

If an underflow occurs, +0 (for rounding modes RN, RZ, RP) or -0 (for rounding mode RM) is stored in register RT.

**Special Registers Altered:**
- FINV
- FINVS
- FOVF
- FOVFS
- FUNF
- FUNFS
- FG
- FX
- FINXS

### Floating-Point Single-Precision Subtract

**EVX-form**

<table>
<thead>
<tr>

### Floating-Point Single-Precision Compare

#### Greater Than

**EVX-form**

```
efscmpgt BF,RA,RB
```

<table>
<thead>
<tr>
<th>4</th>
<th>BF</th>
<th>RA</th>
<th>RB</th>
<th>716</th>
</tr>
</thead>
</table>

\[
\begin{align*}
\text{al} &\leftarrow (\text{RA})_{32:63} \\
\text{bl} &\leftarrow (\text{RB})_{32:63} \\
\text{if} \ (\text{al} > \text{bl}) \ &\text{then} \ cl &\leftarrow 1 \\
\text{else} \ cl &\leftarrow 0 \\
\text{CR}_{4\times\text{BF}+4} &\leftarrow \text{undefined} || cl || \text{undefined} || \text{undefined} \\
\end{align*}
\]

The low element of register RA is compared against the low element of register RB. The results of the comparisons are placed into CR field BF. If RA\text{32-63} is greater than RB\text{32-63}, bit 1 of CR field BF is set to 1, otherwise it is set to 0. Bits 0, 2, and 3 of CR field BF are undefined. Comparison ignores the sign of 0 (+0 = -0).

If an Input Error occurs and default results are generated, NaNs, Infinities, and Denorms are treated as normalized numbers, using their values of ‘e’ and ‘f’ directly.

**Special Registers Altered:**

- FINV
- FINVS
- FG
- FX
- CR field BF

#### Less Than

**EVX-form**

```
efscmplt BF,RA,RB
```

<table>
<thead>
<tr>
<th>4</th>
<th>BF</th>
<th>RA</th>
<th>RB</th>
<th>717</th>
</tr>
</thead>
</table>

\[
\begin{align*}
\text{al} &\leftarrow (\text{RA})_{32:63} \\
\text{bl} &\leftarrow (\text{RB})_{32:63} \\
\text{if} \ (\text{al} < \text{bl}) \ &\text{then} \ cl &\leftarrow 1 \\
\text{else} \ cl &\leftarrow 0 \\
\text{CR}_{4\times\text{BF}+4} &\leftarrow \text{undefined} || cl || \text{undefined} || \text{undefined} \\
\end{align*}
\]

The low element of register RA is compared against the low element of register RB. If RA\text{32-63} is less than RB\text{32-63}, bit 1 of CR field BF is set to 1, otherwise it is set to 0. Bits 0, 2, and 3 of CR field BF are undefined. Comparison ignores the sign of 0 (+0 = -0).

If an Input Error occurs and default results are generated, NaNs, Infinities, and Denorms are treated as normalized numbers, using their values of ‘e’ and ‘f’ directly.

**Special Registers Altered:**

- FINV
- FINVS
- FG
- FX
- CR field BF
Floating-Point Single-Precision Compare Equal

`efscmpeq BF,RA,RB`

```
4
BF // RA  RB  718
0  32:63 35
1  32:63 35
```

```
al ← (RA)_{32:63}
bl ← (RB)_{32:63}
if (al = bl) then cl ← 1
else cl ← 0
CR_{4×BF:4×BF+3} ← undefined || cl || undefined || undefined
```

The low element of register RA is compared against the low element of register RB. If RA_{32:63} is equal to RB_{32:63}, bit 1 of CR field BF is set to 1, otherwise it is set to 0. Bits 0, 2, and 3 of CR field BF are undefined. Comparison ignores the sign of 0 (+0 = -0).

If an Input Error occurs and default results are generated, NaNs, Infinities, and Denorms are treated as normalized numbers, using their values of ‘e’ and ‘f’ directly.

Special Registers Altered:

<td>4 RT /// 721</td>
</tr>
</tbody>
</table>

\[ RT_{32:63} \leftarrow \text{CnvtI32ToFp32}((\text{RB})_{32:63}, S, LO, I) \]

The signed integer low element in register RB is converted to a single-precision floating-point value using the current rounding mode and the result is placed into the low element of register RT.

**Special Registers Altered:**
- FINXS
- FG
- FX

### Convert Floating-Point Single-Precision from Unsigned Integer EVX-form

<table>
<thead>
<tr>
<th>Instruction</th>
<th>RT, RB</th>
</tr>
</thead>
<tbody>
<tr>
<td>efscfui</td>
<td>4 RT /// 720</td>
</tr>
</tbody>
</table>

\[ RT_{32:63} \leftarrow \text{CnvtI32ToFp32}((\text{RB})_{32:63}, U, LO, I) \]

The unsigned integer low element in register RB is converted to a single-precision floating-point value using the current rounding mode and the result is placed into the low element of register RT.

**Special Registers Altered:**
- FINXS
- FG
- FX

### Convert Floating-Point Single-Precision from Signed Fraction EVX-form

<table>
<thead>
<tr>
<th>Instruction</th>
<th>RT, RB</th>
</tr>
</thead>
<tbody>
<tr>
<td>efscfsf</td>
<td>4 RT /// 723</td>
</tr>
</tbody>
</table>

\[ RT_{32:63} \leftarrow \text{CnvtI32ToFp32}((\text{RB})_{32:63}, S, LO, F) \]

The signed fractional low element in register RB is converted to a single-precision floating-point value using the current rounding mode and the result is placed into the low element of register RT.

**Special Registers Altered:**
- FINXS
- FG
- FX

### Convert Floating-Point Single-Precision from Unsigned Fraction EVX-form

<table>
<thead>
<tr>
<th>Instruction</th>
<th>RT, RB</th>
</tr>
</thead>
<tbody>
<tr>
<td>efscfuf</td>
<td>4 RT /// 722</td>
</tr>
</tbody>
</table>

\[ RT_{32:63} \leftarrow \text{CnvtI32ToFp32}((\text{RB})_{32:63}, U, LO, F) \]

The unsigned fractional low element in register RB is converted to a single-precision floating-point value using the current rounding mode and the result is placed into the low element of register RT.

**Special Registers Altered:**
- FINXS
- FG
- FX

### Convert Floating-Point Single-Precision to Signed Integer EVX-form

<table>
<thead>
<tr>

9.3.4 SPE.Embedded Float Scalar Double Instructions
[Category: SPE.Embedded Float Scalar Double]

Floating-Point Double-Precision Absolute Value

\[ \text{efdabs } \text{RT}, \text{RA} \]

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
| & 4 & \text{RT} & \text{RA} & /// & 740 \\
\hline
\end{array}
\]

\[ \text{RT}_{0:63} \leftarrow 0b0 || \langle \text{RA} \rangle_{1:63} \]

The sign bit of register RA is set to 0 and the result is placed in register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

Special Registers Altered:
None

Floating-Point Double-Precision Negative Absolute Value

\[ \text{efdnabs } \text{RT}, \text{RA} \]

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
| & 4 & \text{RT} & \text{RA} & /// & 741 \\
\hline
\end{array}
\]

\[ \text{RT}_{0:63} \leftarrow 0b1 || \langle \text{RA} \rangle_{1:63} \]

The sign bit of register RA is set to 1 and the result is placed in register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

Special Registers Altered:
None

Floating-Point Double-Precision Negate

\[ \text{efdneg } \text{RT}, \text{RA} \]

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
| & 4 & \text{RT} & \text{RA} & /// & 742 \\
\hline
\end{array}
\]

\[ \text{RT}_{0:63} \leftarrow \neg \langle \text{RA} \rangle_{0} || \langle \text{RA} \rangle_{1:63} \]

The sign bit of register RA is complemented and the result is placed in register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

Special Registers Altered:
None
Floating-Point Double-Precision Add
EVX-form

efdadd RT,RA,RB

RT₀:63 ← (RA)₀:63 +dp (RB)₀:63
RA is added to RB and the result is stored in register RT.
If an underflow occurs, +0 (for rounding modes RN, RZ, RP) or -0 (for rounding mode RM) is stored in register RT.

Special Registers Altered:
FINV FINVS
FOVF FOVFS
FUNF FUNFS
FG FX FINXS

Floating-Point Double-Precision Subtract
EVX-form

efdsub RT,RA,RB

RT₀:63 ← (RA)₀:63 -dp (RB)₀:63
RB is subtracted from RA and the result is stored in register RT.
If an underflow occurs, +0 (for rounding modes RN, RZ, RP) or -0 (for rounding mode RM) is stored in register RT.

Special Registers Altered:
FINV FINVS
FOVF FOVFS
FUNF FUNFS
FG FX FINXS

Floating-Point Double-Precision Multiply
EVX-form

efdmul RT,RA,RB

RT₀:63 ← (RA)₀:63 ×dp (RB)₀:63
RA is multiplied by RB and the result is stored in register RT.

Special Registers Altered:
FINV FINVS
FOVF FOVFS
FUNF FUNFS
FG FX FINXS

Floating-Point Double-Precision Divide
EVX-form

efddiv RT,RA,RB

RT₀:63 ← (RA)₀:63 ÷dp (RB)₀:63
RA is divided by RB and the result is stored in register RT.

Special Registers Altered:
FINV FINVS
FG FX FINXS
FDBZ FDBZS
FOVF FOVFS
FUNF FUNFS
### Floating-Point Double-Precision Compare Greater Than EVX-form

<table>
<thead>
<tr>
<th></th>
<th>4</th>
<th>BF</th>
<th>RA</th>
<th>RB</th>
<th>748</th>
</tr>
</thead>
</table>

\[
\begin{align*}
\text{al} & \leftarrow (\text{RA})_{0:63} \\
\text{bl} & \leftarrow (\text{RB})_{0:63} \\
\text{if} (\text{al} > \text{bl}) & \text{ then } \text{cl} \leftarrow 1 \\
\text{else cl} & \leftarrow 0 \\
\text{CR}_{4 \times \text{BF}:4 \times \text{BF}+3} & \leftarrow \underline{\text{undefined}} || \text{cl} || \underline{\text{undefined}} || \underline{\text{undefined}}
\end{align*}
\]

RA is compared against RB. If RA is greater than RB, bit 1 of CR field BF is set to 1, otherwise it is set to 0. Bits 0, 2, and 3 of CR field BF are undefined. Comparison ignores the sign of 0 (+0 = -0).

If an input error occurs and default results are generated, NaNs, Infinities, and Denorms are treated as normalized numbers, using their values of ‘e’ and ‘f’ directly.

**Special Registers Altered:**
- FINV
- FINVS
- FG
- FX
- CR field BF

### Floating-Point Double-Precision Compare Equal EVX-form

<table>
<thead>
<tr>
<th></th>
<th>4</th>
<th>BF</th>
<th>RA</th>
<th>RB</th>
<th>750</th>
</tr>
</thead>
</table>

\[
\begin{align*}
\text{al} & \leftarrow (\text{RA})_{0:63} \\
\text{bl} & \leftarrow (\text{RB})_{0:63} \\
\text{if} (\text{al} = \text{bl}) & \text{ then } \text{cl} \leftarrow 1 \\
\text{else cl} & \leftarrow 0 \\
\text{CR}_{4 \times \text{BF}:4 \times \text{BF}+3} & \leftarrow \underline{\text{undefined}} || \text{cl} || \underline{\text{undefined}} || \underline{\text{undefined}}
\end{align*}
\]

RA is compared against RB. If RA is equal to RB, bit 1 of CR field BF is set to 1, otherwise it is set to 0. Bits 0, 2, and 3 of CR field BF are undefined. Comparison ignores the sign of 0 (+0 = -0).

If an input error occurs and default results are generated, NaNs, Infinities, and Denorms are treated as normalized numbers, using their values of ‘e’ and ‘f’ directly.

**Special Registers Altered:**
- FINV
- FINVS
- FG
- FX
- CR field BF

### Floating-Point Double-Precision Compare Less Than EVX-form

<table>
<thead>
<tr>
<th></th>
<th>4</th>
<th>BF</th>
<th>RA</th>
<th>RB</th>
<th>749</th>
</tr>
</thead>
</table>

\[
\begin{align*}
\text{al} & \leftarrow (\text{RA})_{0:63} \\
\text{bl} & \leftarrow (\text{RB})_{0:63} \\
\text{if} (\text{al} < \text{bl}) & \text{ then } \text{cl} \leftarrow 1 \\
\text{else cl} & \leftarrow 0 \\
\text{CR}_{4 \times \text{BF}:4 \times \text{BF}+3} & \leftarrow \underline{\text{undefined}} || \text{cl} || \underline{\text{undefined}} || \underline{\text{undefined}}
\end{align*}
\]

RA is compared against RB. If RA is less than RB, bit 1 of CR field BF is set to 1, otherwise it is set to 0. Bits 0, 2, and 3 of CR field BF are undefined. Comparison ignores the sign of 0 (+0 = -0).

If an input error occurs and default results are generated, NaNs, Infinities, and Denorms are treated as normalized numbers, using their values of ‘e’ and ‘f’ directly.

**Special Registers Altered:**
- FINV
- FINVS
- FG
- FX
- CR field BF

### Floating-Point Double-Precision Test Greater Than EVX-form

<table>
<thead>
<tr>
<th></th>
<th>4</th>
<th>BF</th>
<th>RA</th>
<th>RB</th>
<th>764</th>
</tr>
</thead>
</table>

\[
\begin{align*}
\text{al} & \leftarrow (\text{RA})_{0:63} \\
\text{bl} & \leftarrow (\text{RB})_{0:63} \\
\text{if} (\text{al} > \text{bl}) & \text{ then } \text{cl} \leftarrow 1 \\
\text{else cl} & \leftarrow 0 \\
\text{CR}_{4 \times \text{BF}:4 \times \text{BF}+3} & \leftarrow \underline{\text{undefined}} || \text{cl} || \underline{\text{undefined}} || \underline{\text{undefined}}
\end{align*}
\]

RA is compared against RB. If RA is greater than RB, bit 1 of CR field BF is set to 1, otherwise it is set to 0. Bits 0, 2, and 3 of CR field BF are undefined. Comparison ignores the sign of 0 (+0 = -0). The comparison proceeds after treating NaNs, Infinities, and Denorms as normalized numbers, using their values of ‘e’ and ‘f’ directly.

No exceptions are generated during the execution of `efdtstgt`.

**Special Registers Altered:**
- CR field BF

---

### Programming Note

In an implementation, the execution of `efdtstgt` is likely to be faster than the execution of `efdcmpgt`; however, if strict IEEE 754 compliance is required, the program should use `efdcmpgt`.

  4  6  11  16  21  758
```

The double-precision floating-point value in register RB is converted to an unsigned fraction using the current rounding mode and the result is saturated if it cannot be represented in a 32-bit unsigned fraction. NaNs are converted as though they were zero.

**Corequisite Categories:**
- SPE.Embedded Float Scalar Single or SPE.Embedded Float Vector

**Special Registers Altered:**
- FINV
- FINVS
- FINXS
- FG
- FX

---

**Floating-Point Double-Precision Convert from Single-Precision**

**EVX-form**

efdcs  RT, RB

```
  4  6  11  16  21  751
```

The single-precision floating-point value in the low element of register RB is converted to a double-precision floating-point value and the result is placed in register RT.

**Corequisite Categories:**
- SPE.Embedded Float scalar Single or SPE.Embedded Float Vector

**Special Registers Altered:**
- FINV
- FINVS
- FINXS
- FG
- FX
Floating-Point Single-Precision Convert
from Double-Precision EVX-form

```
efscfd RT,RB

FP64format f;
FP32format result;
f ← (RB)[0:63]
if (fexp = 0) & (ffrac = 0)) then
    result ← fsign || 310
else if Is64NaNorInfinity(f) then
    SPEFSCRFINV ← 1
    result ← fsign || 0b11111110 || 231
else if Is64Denorm(f) then
    SPEFSCRFINV ← 1
    result ← fsign || 310
else
    unbias ← fexp - 1023
    if unbias > 127 then
        result ← fsign || 0b11111110 || 231
        SPEFSCR_FOVF ← 1
    else if unbias < -126 then
        result ← fsign || 310
        SPEFSCR_FUNF ← 1
    else
        resultsign ← fsign
        resultexp ← unbias + 127
        resultfrac ← ffrac[0:22]
guard ← ffrac[23]
sticky ← (ffrac[24:51] ≠ 0)
result ← Round32(result, LO, guard, sticky)

SPEFSCR_FG ← guard
SPEFSCR_FX ← sticky
if guard | sticky then
    SPEFSCR_FINXS ← 1

RT[32:63] ← result
```

The double-precision floating-point value in register RB is converted to a single-precision floating-point value using the current rounding mode and the result is placed into the low element of register RT.

Corequisite Categories:
SPE.Embedded Float Scalar Scalar

Special Registers Altered:
FINV FINVS
FOVF FOVFS
FUNF FUNFS
FG FX FINXS
9.4 Embedded Floating-Point Results Summary

The following tables summarize the results of various types of Embedded Floating-Point operations on various combinations of input operands. Flag settings are performed on appropriate element flags. For all the tables the following annotation and general rules apply:

- "*" denotes that this status flag is set based on the results of the calculation.
- "Calc_" denotes that the result is updated with the results of the computation.
- "max" denotes the maximum normalized number with the sign set to the computation [sign(operand A) XOR sign(operand B)].
- "amax" denotes the maximum normalized number with the sign set to the sign of Operand A.
- "bmax" denotes the maximum normalized number with the sign set to the sign of Operand B.
- "pmax" denotes the maximum normalized positive number. The encoding for single-precision is: 0x7F7FFFFF. The encoding for double-precision is: 0x7FEFFFFF_FFFFFFFF.
- "nmax" denotes the maximum normalized negative number. The encoding for single-precision is: 0xFF7FFFFF. The encoding for double-precision is: 0xFFEFFFFF_FFFFFFFF.
- "pmin" denotes the minimum normalized positive number. The encoding for single-precision is: 0x00800000. The encoding for double-precision is: 0x00100000_00000000.
- "nmin" denotes the minimum normalized negative number. The encoding for single-precision is: 0x80800000. The encoding for double-precision is: 0x80100000_00000000.
- Calculations that overflow or underflow saturate. Overflow for operations that have a floating-point result force the result to "max". Underflow for operations that have a floating-point result force the result to zero. Overflow for operations that have a signed integer result force the result to 0x7FFFFFFF (positive) or 0x80000000 (negative). Underflow for operations that have an unsigned integer result force the result to 0xFFFFFFF (positive) or 0x00000000 (negative).
- 1 (superscript) denotes that the sign of the result is positive when the sign of Operand A and the sign of Operand B are different, for all rounding modes except round to -infinity, where the sign of the result is then negative.
- 2 (superscript) denotes that the sign of the result is positive when the sign of Operand A and the sign of Operand B are the same, for all rounding modes except round to -infinity, where the sign of the result is then negative.
- 3 (superscript) denotes that the sign for any multiply or divide is always the result of the operation [sign(Operand A) XOR sign(Operand B)].
- 4 (superscript) denotes that if an overflow is detected, the result may be saturated.

Chapter 10. Legacy Move Assist Instruction
[Category: Legacy Move Assist]

Determine Leftmost Zero Byte  

\[ \text{dlmzb} \quad RA, RS, RB \quad (Rc=0) \]
\[ \text{dlmzb.} \quad RA, RS, RB \quad (Rc=1) \]

\[
\begin{array}{cccccc}
\text{do while } (x<8) \& (y=0) \\
\text{x} & \leftarrow & x + 1 \\
\text{if } d_i+32:39 \text{ } = \text{ } 0 & \text{then} \\
\text{y} & \leftarrow & 1 \\
\text{else} \\
\text{i} & \leftarrow & i + 8 \\
\text{x} & \leftarrow & (RS)_{32:63} || (RB)_{32:63} \\
\text{y} & \leftarrow & 0 \\
\text{enddo} & \quad \text{if } \text{Rc} = \text{1} & \text{do} & \quad \text{else} \\
\text{i} & \leftarrow & 0 \\
\text{x} & \leftarrow & x \\
\text{XER}_{57:63} & \leftarrow & x \\
\text{if } \text{Rc} = \text{1} & \text{then} & \text{CR}_{35} & \leftarrow & \text{SO} & \quad \text{if } \text{y} = \text{1} & \text{then} & \text{if } \text{x} < \text{5} & \text{then} & \text{CR}_{32:34} & \leftarrow & 0b010 \\
\text{else} & \quad \text{else} & \text{CR}_{32:34} & \leftarrow & 0b100 \\
\text{else} & \quad \text{else} & \text{CR}_{32:34} & \leftarrow & 0b001 \\
\end{array}
\]

The contents of bits 32:63 of register RS and the contents of bits 32:63 of register RB are concatenated to form an 8-byte operand. The operand is searched for the leftmost byte in which each bit is 0 (i.e., a null byte).

Bytes in the operand are numbered from left to right starting with 1. If a null byte is found, its byte number is placed into bits 57:63 of the XER and into register RA. Otherwise, the value \(0b000 \ 1000\) is placed into both bits 57:63 of the XER and register RA.

If Rc is equal to 1, SO is copied into bit 35 of the CR and bits 32:34 of the CR are updated as follows:

- If no null byte is found, bits 32:34 of the CR are set to \(0b001\).
- If the leftmost null byte is in the first 4 bytes (i.e., from register RS), bits 32:34 of the CR are set to \(0b010\).
- If the leftmost null byte is in the last 4 bytes (i.e., from register RB), bits 32:34 of the CR are set to \(0b100\).
Chapter 11. Legacy Integer Multiply-Accumulate Instructions [Category: Legacy Integer Multiply-Accumulate]

The Legacy Integer Multiply-Accumulate instructions with Rc=1 set the first three bits of CR Field 0 based on the 32-bit result, as described in Section 3.3.8, “Other Fixed-Point Instructions”.

The XO-form Legacy Integer Multiply-Accumulate instructions set SO and OV when OE=1 to reflect overflow of the 32-bit result.

### Multiply Accumulate Cross Halfword to Word Modulo Signed

<table>

</table>

macchw RT,RA,RB (OE=0 Rc=0)
machch. RT,RA,RB (OE=0 Rc=1)
machchwo RT,RA,RB (OE=1 Rc=0)
machchwo. RT,RA,RB (OE=1 Rc=1)

\[
\begin{align*}
\text{prod}_{0:31} & \leftarrow (\text{RA})_{48:63} \times_{\text{si}} (\text{RB})_{32:47} \\
\text{temp}_{0:32} & \leftarrow \text{prod}_{0:31} + (\text{RT})_{32:63} \\
\text{RT}_{32:63} & \leftarrow \text{temp}_{1:32} \\
\text{RT}_{0:31} & \leftarrow \text{undefined}
\end{align*}
\]

The signed-integer halfword in bits 48:63 of register RA is multiplied by the signed-integer halfword in bits 32:47 of register RB.

The 32-bit signed-integer product is added to the signed-integer word in bits 32:63 of register RT.

The low-order 32 bits of the sum are placed into bits 32:63 of register RT.

The contents of bits 0:31 of register RT are undefined.

**Special Registers Altered:**
- SO OV (if OE=1)
- CR0 (if Rc=1)

### Multiply Accumulate Cross Halfword to Word Saturate Signed

<table>
<thead>

</tbody>
</table>

macchws RT,RA,RB (OE=0 Rc=0)
machchws. RT,RA,RB (OE=0 Rc=1)
machchwso RT,RA,RB (OE=1 Rc=0)
machchwso. RT,RA,RB (OE=1 Rc=1)

\[
\begin{align*}
\text{prod}_{0:31} & \leftarrow (\text{RA})_{48:63} \times_{\text{si}} (\text{RB})_{32:47} \\
\text{temp}_{0:32} & \leftarrow \text{prod}_{0:31} + (\text{RT})_{32:63} \\
\text{if temp} & < -2^{31} \quad \text{then} \quad \text{RT}_{32:63} \leftarrow 0x8000_0000 \\
\text{else if temp} & > 2^{31}-1 \quad \text{then} \quad \text{RT}_{32:63} \leftarrow 0x7FFF_FFFF \\
\text{else} & \quad \text{RT}_{32:63} \leftarrow \text{temp}_{1:32} \\
\text{RT}_{0:31} & \leftarrow \text{undefined}
\end{align*}
\]

The signed-integer halfword in bits 48:63 of register RA is multiplied by the signed-integer halfword in bits 32:47 of register RB.

The 32-bit signed-integer product is added to the signed-integer word in bits 32:63 of register RT.

If the sum is less than -2^{31}, then the value 0x8000_0000 is placed into bits 32:63 of register RT.

If the sum is greater than 2^{31}-1, then the value 0x7FFF_FFFF is placed into bits 32:63 of register RT.

Otherwise, the sum is placed into bits 32:63 of register RT.

The contents of bits 0:31 of register RT are undefined.

**Special Registers Altered:**
- SO OV (if OE=1)
- CR0 (if Rc=1)

Programming Note

Notice that CR Field 0 may not reflect the “true” (infinitely precise) result if overflow occurs.
### Multiply Accumulate Cross Halfword to Word Modulo Unsigned XO-form

```

```
prod0:31 ← (RA)48:63 ×ui (RB)48:63
temp0:32 ← prod0:31 + (RT)32:63
RT32:63 ← temp1:32
RT0:31 ← undefined
```

The unsigned-integer halfword in bits 48:63 of register RA is multiplied by the unsigned-integer halfword in bits 48:63 of register RB.

The 32-bit unsigned-integer product is added to the unsigned-integer word in bits 32:63 of register RT.

The low-order 32 bits of the sum are placed into bits 32:63 of register RT.

The contents of bits 0:31 of register RT are undefined.

\text{FRT} & \leftarrow 0xBFF0\_0000\_0000\_0000 \\
\text{ /* value = -1.0 */ } \\
\text{FPSCR}_{\text{FPRF}} & \leftarrow "-\text{ normal number}" \\
\text{End} \\
\text{FPSCR}_{\text{FR FI}} & \leftarrow 0b00 \\
\text{Done}
\end{align*}
\]

Large Operand:

\[
\begin{align*}
\text{FRT} & \leftarrow (\text{FRB})
\end{align*}
\]
Appendix B. Densely Packed Decimal

The trailing significand field of the decimal floating-point data format is encoded using Densely Packed Decimal (DPD). DPD encoding is a compression technique which supports the representation of decimal integers of arbitrary length. Translation operates on three Binary Coded Decimal (BCD) digits at a time compressing the 12 bits into 10 bits with an algorithm that can be applied or reversed using simple Boolean operations. In the following examples, a 3-digit BCD number is represented as (abcd)(efgh)(ijklm), a 10-bit DPD number is represented as (pqrstuv)(wxyz), and the Boolean operations, & (AND), | (OR), and ~ (NOT) are used.

B.1 BCD-to-DPD Translation

The translation from a 3-digit BCD number to a 10-bit DPD can be performed through the following Boolean operations.

\[
\begin{align*}
p &= (f \& a \& i \& \neg e) \mid (j \& a \& \neg i) \mid (b \& \neg a) \\
q &= (g \& a \& i \& \neg e) \mid (k \& a \& \neg i) \mid (c \& \neg a) \\
r &= d \\
s &= (j \& \neg a \& e \& \neg i) \mid (f \& \neg i \& \neg e) \\
t &= (k \& \neg a \& e \& \neg i) \mid (g \& \neg i \& \neg e) \\
u &= h \\
v &= a \mid e \mid i \\
w &= (\neg e \& j \& \neg i) \mid (e \& i) \mid a \\
x &= (\neg a \& k \& \neg i) \mid (a \& i) \mid e \\
y &= m
\end{align*}
\]

Alternatively, the following table can be used to perform the translation. The most significant bit of the three BCD digits (left column) is used to select a specific 10-bit encoding (right column) of the DPD.

<table>
<thead>
<tr>
<th>sei</th>
<th>pqr stu v wxy</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>bcd fgh 0 jkm</td>
</tr>
<tr>
<td>001</td>
<td>bcd fgh 1 00m</td>
</tr>
<tr>
<td>010</td>
<td>bcd jkh 1 01m</td>
</tr>
<tr>
<td>011</td>
<td>bcd 10h 1 11m</td>
</tr>
<tr>
<td>100</td>
<td>jkd fgh 1 10m</td>
</tr>
<tr>
<td>101</td>
<td>fgd 01h 1 11m</td>
</tr>
<tr>
<td>110</td>
<td>jkd 00h 1 11m</td>
</tr>
<tr>
<td>111</td>
<td>00d 11h 1 11m</td>
</tr>
</tbody>
</table>

The full translation of a 3-digit BCD number (000 - 999) to a 10-bit DPD is shown in Table 123 on page 699.

B.2 DPD-to-BCD Translation

The translation from a 10-bit DPD to a 3-digit BCD number can be performed through the following Boolean operations.

\[
\begin{align*}
a &= (\neg s \& v \& w) \mid (t \& v \& w \& s) \mid (v \& w \& \neg x) \\
b &= (p \& s \& x \& \neg t) \mid (p \& \neg w) \mid (p \& \neg v) \\
c &= (q \& s \& x \& \neg t) \mid (q \& \neg w) \mid (q \& \neg v) \\
d &= r \\
e &= (v \& \neg w \& x) \mid (s \& v \& w \& x) \mid (\neg t \& v \& x \& w) \\
f &= (p \& t \& v \& w \& x \& \neg s) \mid (s \& \neg x \& v) \mid (s \& \neg v) \\
g &= (q \& t \& w \& v \& x \& \neg s) \mid (t \& \neg x \& v) \mid (t \& \neg v) \\
h &= u \\
i &= (t \& v \& w \& x) \mid (s \& v \& w \& x) \mid (v \& \neg w \& \neg x) \\
j &= (p \& \neg s \& \neg t \& w \& v) \mid (s \& v \& \neg w \& x) \mid (p \& w \& \neg x \& v) \mid (w \& \neg v) \\
k &= (q \& \neg s \& \neg t \& v \& w) \mid (t \& v \& \neg w \& x) \mid (q \& v \& w \& \neg x) \mid (x \& \neg v) \\
m &= y
\end{align*}
\]

Alternatively, the following table can be used to perform the translation. A combination of five bits in the DPD encoding (leftmost column) are used to specify a translation to the 3-digit BCD encoding. Dashes (-) in the table are don’t cares, and can be either one or zero.
The full translation of the 10-bit DPD to a 3-digit BCD number is shown in Table 124 on page 700. The 10-bit DPD index is produced by concatenating the 6-bit value shown in the left column with the 4-bit index along the top row, both represented in hexadecimal. The values in parentheses are non-preferred translations and are explained further in the following section.

### B.3 Preferred DPD encoding

Translating from a 3-digit BCD number (1000 numbers) to a 10-bit DPD encoding (1024 combinations) leaves 24 redundant translations. The 24 redundant combinations are evenly assigned to eight BCD numbers and are shown in the following table, with the non-preferred encoding in parentheses. The preferred encoding is produced by translating a 3-digit BCD number with the translation table or Boolean operations shown in Section B.1. The redundant DPD encodings are all valid and will be correctly translated to their respective BCD value through the mechanisms provided in Section B.2. For decimal floating-point operations all DPD encodings are recognized as source operands.

Appendix E. Assembler Extended Mnemonics

In order to make assembler language programs simpler to write and easier to understand, a set of extended mnemonics and symbols is provided that defines simple shorthand for the most frequently used forms of Branch Conditional, Compare, Trap, Rotate and Shift, and certain other instructions.

Assemblers should provide the extended mnemonics and symbols listed here, and may provide others.

E.1 Symbols

The following symbols are defined for use in instructions (basic or extended mnemonics) that specify a Condition Register field or a Condition Register bit. The first five (lt, ..., un) identify a bit number within a CR field. The remainder (cr0, ..., cr7) identify a CR field. An expression in which a CR field symbol is multiplied by 4 and then added to a bit-number-within-CR-field symbol and 32 can be used to identify a CR bit.

</tbody>
</table>

The extended mnemonics in Sections E.2.2 and E.3 require identification of a CR bit: if one of the CR field symbols is used, it must be multiplied by 4 and added to a bit-number-within-CR-field (value in the range 0-3, explicit or symbolic) and 32. The extended mnemonics in Sections E.2.3 and E.5 require identification of a CR field: if one of the CR field symbols is used, it must not be multiplied by 4 or added to 32. (For the extended mnemonics in Section E.2.3, the bit number within the CR field is part of the extended mnemonic. The programmer identifies the CR field, and the Assembler does the multiplication and addition required to produce a CR bit number for the BI field of the underlying basic mnemonic.)
E.2 Branch Mnemonics

The mnemonics discussed in this section are variations of the Branch Conditional instructions.

Note: bclr, bclrl, bcctr, and bcctrl each serve as both a basic and an extended mnemonic. The Assembler will recognize a bclr, bclrl, bcctr, or bcctrl mnemonic with three operands as the basic form, and a bclr, bclrl, bcctr, or bcctrl mnemonic with two operands as the extended form. In the extended form the BH operand is omitted and assumed to be 0b00. Similarly, for all the extended mnemonics described in Sections E.2.2 - E.2.4 that devolve to any of these four basic mnemonics the BH operand can either be coded or omitted. If it is omitted it is assumed to be 0b00.

E.2.1 BO and BI Fields

The 5-bit BO and BI fields control whether the branch is taken. Providing an extended mnemonic for every possible combination of these fields would be neither useful nor practical. The mnemonics described in Sections E.2.2 - E.2.4 include the most useful cases. Other cases can be coded using a basic Branch Conditional mnemonic (bc[l][a], bclr[l], bcctr[l]) with the appropriate operands.

E.2.2 Simple Branch Mnemonics

Instructions using one of the mnemonics in Table 125 that tests a Condition Register bit specify the corresponding bit as the first operand. The symbols defined in Section E.1 can be used in this operand.

Notice that there are no extended mnemonics for relative and absolute unconditional branches. For these the basic mnemonics b, ba, bl, and bla should be used.

</tr>
</tbody>
</table>

Examples

1. Decrement CTR and branch if it is still nonzero (closure of a loop controlled by a count loaded into CTR).
   
   bdnz target (equivalent to: bc 16,0,target)

2. Same as (1) but branch only if CTR is nonzero and condition in CR0 is "equal".
   
   bdnzt eq,target (equivalent to: bc 8,2,target)

3. Same as (2), but "equal" condition is in CR5.
   
   bdnzt 4×cr5+eq,target (equivalent to: bc 8,22,target)
4. Branch if bit 59 of CR is 0.
   \texttt{bf} 27,target  \quad (equivalent to:  \texttt{bc} 4,27,target)

5. Same as (4), but set the Link Register. This is a form of conditional “call”.
   \texttt{bfl} 27,target  \quad (equivalent to:  \texttt{bcl} 4,27,target)

### E.2.3 Branch Mnemonics Incorporating Conditions

In the mnemonics defined in Table 126, the test of a bit in a Condition Register field is encoded in the mnemonic.

Instructions using the mnemonics in Table 126 specify the CR field as an optional first operand. One of the CR field symbols defined in Section E.1 can be used for this operand. If the CR field being tested is CR Field 0, this operand need not be specified unless the resulting basic mnemonic is \texttt{bclr} or \texttt{bcctr} and the BH operand is specified.

A standard set of codes has been adopted for the most common combinations of branch conditions.

<table>

</tbody>
</table>

### Examples

1. Branch if CR0 reflects condition “not equal”.
   \texttt{bne} target  \quad (equivalent to:  \texttt{bc} 4,2,target)

2. Same as (1), but condition is in CR3.
bne cr3,target (equivalent to: bc 4,14,target)

3. Branch to an absolute target if CR4 specifies “greater than”, setting the Link Register. This is a form of conditional “call”.
   bgta cr4,target (equivalent to: bcla 12,17,target)

4. Same as (3), but target address is in the Count Register.
   bgtctrl cr4 (equivalent to: bcctrl 12,17,0)

**E.2.4 Branch Prediction**

Software can use the “at” bits of *Branch Conditional* instructions to provide a hint to the processor about the behavior of the branch. If, for a given such instruction, the branch is almost always taken or almost always not taken, a suffix can be added to the mnemonic indicating the value to be used for the “at” bits.

+ Predict branch to be taken (at=0b11)
- Predict branch not to be taken (at=0b10)

Such a suffix can be added to any *Branch Conditional* mnemonic, either basic or extended, that tests either the Count Register or a CR bit (but not both). Assemblers should use 0b00 as the default value for the “at” bits, indicating that software has offered no prediction.

**Examples**

1. Branch if CR0 reflects condition “less than”, specifying that the branch should be predicted to be taken.
   blt+ target

2. Same as (1), but target address is in the Link Register and the branch should be predicted not to be taken.
   bltlr-
E.3 Condition Register Logical Mnemonics

The Condition Register Logical instructions can be used to set (to 1), clear (to 0), copy, or invert a given Condition Register bit. Extended mnemonics are provided that allow these operations to be coded easily.

Table 127: Condition Register logical mnemonics

<table>
<thead>
<tr>
<th>Operation</th>
<th>Extended Mnemonic</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Condition Register set</td>
<td>crset bx</td>
<td>creqv bx,bx,bx</td>
</tr>
<tr>
<td>Condition Register clear</td>
<td>crclr bx</td>
<td>crxor bx,bx,bx</td>
</tr>
<tr>
<td>Condition Register move</td>
<td>crmove bx,by</td>
<td>cror bx,by,by</td>
</tr>
<tr>
<td>Condition Register not</td>
<td>crnot bx,by</td>
<td>cmor bx,by,by</td>
</tr>
</tbody>
</table>

The symbols defined in Section E.1 can be used to identify the Condition Register bits.

Examples
1. Set CR bit 57.
   
   crset 25 (equivalent to: creqv 25,25,25)
2. Clear the SO bit of CR0.
   
   crclr so (equivalent to: crxor 3,3,3)
3. Same as (2), but SO bit to be cleared is in CR3.
   
   crclr 4x cr3+so (equivalent to: crxor 15,15,15)
4. Invert the EQ bit.
   
   crnot eq,eq (equivalent to: cmor 2,2,2)
5. Same as (4), but EQ bit to be inverted is in CR4, and the result is to be placed into the EQ bit of CR5.
   
   crnot 4x cr5+eq,4x cr4+eq (equivalent to: cmor 22,18,18)

E.4 Subtract Mnemonics

E.4.1 Subtract Immediate

Although there is no “Subtract Immediate” instruction, its effect can be achieved by using an Add Immediate instruction with the immediate operand negated. Extended mnemonics are provided that include this negation, making the intent of the computation clearer.

   subi Rx,Ry,value (equivalent to: addi Rx,Ry,-value)
   subis Rx,Ry,value (equivalent to: addis Rx,Ry,-value)
   subic Rx,Ry,value (equivalent to: addic Rx,Ry,-value)
   subic Rx,Ry,value (equivalent to: addic Rx,Ry,-value)

E.4.2 Subtract

The Subtract From instructions subtract the second operand (RA) from the third (RB). Extended mnemonics are provided that use the more “normal” order, in which the third operand is subtracted from the second. Both these mnemonics can be coded with a final “o” and/or “c” to cause the OE and/or Rc bit to be set in the underlying instruction.

   sub Rx,Ry,Rz (equivalent to: subf Rx,Rz,Ry)
   subc Rx,Ry,Rz (equivalent to: subfc Rx,Rz,Ry)
E.5 Compare Mnemonics

The L field in the fixed-point Compare instructions controls whether the operands are treated as 64-bit quantities or as 32-bit quantities. Extended mnemonics are provided that represent the L value in the mnemonic rather than requiring it to be coded as a numeric operand.

The BF field can be omitted if the result of the comparison is to be placed into CR Field 0. Otherwise the target CR field must be specified as the first operand. One of the CR field symbols defined in Section E.1 can be used for this operand.

Note: The basic Compare mnemonics of Power ISA are the same as those of POWER, but the POWER instructions have three operands while the Power ISA instructions have four. The Assembler will recognize a basic Compare mnemonic with three operands as the POWER form, and will generate the instruction with L=0. (Thus the Assembler must require that the BF field, which normally can be omitted when CR Field 0 is the target, be specified explicitly if L is.)

E.5.1 Doubleword Comparisons

Table 128: Doubleword compare mnemonics

<table>
<thead>
<tr>
<th>Operation</th>
<th>Extended Mnemonic</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compare doubleword immediate</td>

<td>cmpli bf,1,ra,ui</td>
</tr>
<tr>
<td>Compare logical doubleword</td>
<td>cmpld bf,ra,rb</td>
<td>cmpl bf,1,ra,rb</td>
</tr>
</tbody>
</table>

Examples

1. Compare register Rx and immediate value 100 as unsigned 64-bit integers and place result into CR0.
   
   ```
   cmpidi Rx,100
   ```
   (equivalent to:
   ```
   cmpli 0,1,Rx,100
   ```)

2. Same as (1), but place result into CR4.
   
   ```
   cmpidi cr4,Rx,100
   ```
   (equivalent to:
   ```
   cmpli 4,1,Rx,100
   ```)

3. Compare registers Rx and Ry as signed 64-bit integers and place result into CR0.
   
   ```
   cmpd Rx,Ry
   ```
   (equivalent to:
   ```
   cmp 0,1,Rx,Ry
   ```)

E.5.2 Word Comparisons

Table 129: Word compare mnemonics

<table>
<thead>
<tr>
<th>Operation</th>
<th>Extended Mnemonic</th>
<th>Equivalent to</th>

</tr>
<tr>
<td>Compare logical word immediate</td>
<td>cmplwi bf,ra,ui</td>
<td>cmpli bf,0,ra,ui</td>
</tr>
<tr>
<td>Compare logical word</td>
<td>cmplw bf,ra,rb</td>
<td>cmp bf,0,ra,rb</td>
</tr>
</tbody>
</table>

Examples

1. Compare bits 32:63 of register Rx and immediate value 100 as signed 32-bit integers and place result into CR0.
   
   ```
   cmpwi Rx,100
   ```
   (equivalent to:
   ```
   cmpli 0,0,Rx,100
   ```)

2. Same as (1), but place result into CR4.
   
   ```
   cmpwi cr4,Rx,100
   ```
   (equivalent to:
   ```
   cmpli 4,0,Rx,100
   ```)

3. Compare bits 32:63 of registers Rx and Ry as unsigned 32-bit integers and place result into CR0.
   
   ```
   cmplw Rx,Ry
   ```
   (equivalent to:
   ```
   cmp 0,0,Rx,Ry
   ```)
E.6 Trap Mnemonics

The mnemonics defined in Table 130 are variations of the Trap instructions, with the most useful values of TO represented in the mnemonic rather than specified as a numeric operand.

A standard set of codes has been adopted for the most common combinations of trap conditions.

<table>
<thead>

</tbody>
</table>
Examples

1. Trap if register Rx is not 0.
   \[\text{tnei } Rx,0 \quad \text{(equivalent to: } tdi \quad 24,Rx,0)\]

2. Same as (1), but comparison is to register Ry.
   \[\text{tne } Rx,Ry \quad \text{(equivalent to: } td \quad 24,Rx,Ry)\]

3. Trap if bits 32:63 of register Rx, considered as a 32-bit quantity, are logically greater than 0x7FF.
   \[\text{twlgti } Rx,0x7FF \quad \text{(equivalent to: } twi \quad 1,Rx,0x7FF)\]

4. Trap unconditionally.
   \[\text{trap} \quad \text{(equivalent to: } tw \quad 31,0,0)\]

5. Trap unconditionally with immediate parameters Rx and Ry
   \[\text{tdu } Rx,Ry \quad \text{(equivalent to: } td \quad 31,Rx,Ry)\]

E.7 Integer Select Mnemonics

The mnemonics defined in Table 131, “Integer Select mnemonics,” on page 716 are variations of the Integer Select instructions, with the most useful values of BC represented in the mnemonic rather than specified as a numeric operand.

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>lt</td>
<td>Less than</td>
</tr>
<tr>
<td>eq</td>
<td>Equal</td>
</tr>
<tr>
<td>gt</td>
<td>Greater than</td>
</tr>
</tbody>
</table>

These codes are reflected in the mnemonics shown in Table 131.

<table>
<thead>
<tr>
<th>Table 131: Integer Select mnemonics</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Select semantics</strong></td>
</tr>
<tr>
<td>Integer Select if less than</td>
</tr>
<tr>
<td>Integer Select if equal</td>
</tr>
<tr>
<td>Integer Select if greater than</td>
</tr>
</tbody>
</table>

Examples

1. Set register Rx to Ry if the LT bit is set in CR0, and to Rz otherwise.
   \[\text{isellt } Rx,Ry,Rz \quad \text{(equivalent to: } isel \quad Rx,Ry,Rz,0)\]

2. Set register Rx to Ry if the GT bit is set in CR0, and to Rz otherwise.
   \[\text{iselgt } Rx,Ry,Rz \quad \text{(equivalent to: } isel \quad Rx,Ry,Rz,1)\]

3. Set register Rx to Ry if the EQ bit is set in CR0, and to Rz otherwise.
   \[\text{iseleq } Rx,Ry,Rz \quad \text{(equivalent to: } isel \quad Rx,Ry,Rz,2)\]
E.8 Rotate and Shift Mnemonics

The Rotate and Shift instructions provide powerful and general ways to manipulate register contents, but can be difficult to understand. Extended mnemonics are provided that allow some of the simpler operations to be coded easily.

Mnemonics are provided for the following types of operation.

**Extract** Select a field of n bits starting at bit position b in the source register; left or right justify this field in the target register; clear all other bits of the target register to 0.

**Insert** Select a left-justified or right-justified field of n bits in the source register; insert this field starting at bit position b of the target register; leave other bits of the target register unchanged. (No extended mnemonic is provided for insertion of a left-justified field when operating on doublewords, because such an insertion requires more than one instruction.)

**Rotate** Rotate the contents of a register right or left n bits without masking.

**Shift** Shift the contents of a register right or left n bits, clearing vacated bits to 0 (logical shift).

**Clear** Clear the leftmost or rightmost n bits of a register to 0.

**Clear left and shift left**

Clear the leftmost b bits of a register, then shift the register left by n bits. This operation can be used to scale a (known nonnegative) array index by the width of an element.

E.8.1 Operations on Doublewords

All these mnemonics can be coded with a final "." to cause the Rc bit to be set in the underlying instruction.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Extended Mnemonic</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extract and left justify immediate</td>
<td>extldi ra,rs,n,b  (n &gt; 0)</td>
<td>rldicr ra,rs,rb,n-1</td>
</tr>
<tr>
<td>Extract and right justify immediate</td>
<td>extrdi ra,rs,n,b  (n &gt; 0)</td>
<td>rldicl ra,rs,rb,n-64</td>
</tr>
<tr>
<td>Insert from right immediate</td>
<td>insrdi ra,rs,n,b  (n &gt; 0)</td>
<td>rldimi ra,rs,n,64-n,b</td>
</tr>
<tr>
<td>Rotate left immediate</td>

<td>srdi ra,rs,n  (n &lt; 64)</td>
<td>rldicl ra,rs,n,64-n</td>
</tr>
<tr>
<td>Clear left immediate</td>
<td>clrldi ra,rs,n  (n &lt; 64)</td>
<td>rldicl ra,rs,0-n</td>
</tr>
<tr>
<td>Clear right immediate</td>
<td>clrldi ra,rs,n  (n &lt; 64)</td>
<td>rldicl ra,rs,0,63-n</td>
</tr>
<tr>
<td>Clear left and shift left immediate</td>
<td>clrlsldi ra,rs,b,n  (n &lt;= b &lt; 64)</td>
<td>rldic ra,rs,n,b</td>
</tr>
</tbody>
</table>

Examples

1. Extract the sign bit (bit 0) of register Ry and place the result right-justified into register Rx.
   
   `extrdi Rx,Ry,1,0`  (equivalent to:  `rldicl Rx,Ry,1,63`)

2. Insert the bit extracted in (1) into the sign bit (bit 0) of register Rz.
   
   `insrdi Rz,Rx,1,0`  (equivalent to:  `rldimi Rz,Rx,63,0`)

3. Shift the contents of register Rx left 8 bits.
   
   `sldi Rx,Rx,8`  (equivalent to:  `rldicr Rx,Rx,8,55`)

4. Clear the high-order 32 bits of register Ry and place the result into register Rx.
   
   `clrldi Rx,Ry,32`  (equivalent to:  `rldicl Rx,Ry,0,32`)

717  Power ISA™ - Book I
E.8.2 Operations on Words

All these mnemonics can be coded with a final “.” to cause the Rc bit to be set in the underlying instruction. The operations as described above apply to the low-order 32 bits of the registers, as if the registers were 32-bit registers. The Insert operations either preserve the high-order 32 bits of the target register or place rotated data there; the other operations clear these bits.

Examples

1. Extract the sign bit (bit 32) of register Ry and place the result right-justified into register Rx.
   extrwi Rx,Ry,1,0 (equivalent to: rlwinm Rx,Ry,1,31,31)
2. Insert the bit extracted in (1) into the sign bit (bit 32) of register Rz.
   insrwi Rz,Rx,1,0 (equivalent to: rlwimi Rz,Rx,31,0,0)
3. Shift the contents of register Rx left 8 bits, clearing the high-order 32 bits.
   slwi Rx,Rx,8 (equivalent to: rlwinm Rx,Rx,8,0,23)
4. Clear the high-order 16 bits of the low-order 32 bits of register Ry and place the result into register Rx, clearing the high-order 32 bits of register Rx.
   clrlwi Rx,Ry,16 (equivalent to: rlwinm Rx,Ry,0,16,31)
E.9 Move To/From Special Purpose Register Mnemonics

The `mtspr` and `mfspr` instructions specify a Special Purpose Register (SPR) as a numeric operand. Extended mnemonics are provided that represent the SPR in the mnemonic rather than requiring it to be coded as an operand.

### Examples

1. Copy the contents of register Rx to the XER.
   ```assembly
   mtxer Rx  \(\text{equivalent to: } \text{mtspr } 1, Rx\)
   ```

2. Copy the contents of the LR to register Rx.
   ```assembly
   mflr Rx  \(\text{equivalent to: } \text{mfspr } Rx, 8\)
   ```

3. Copy the contents of register Rx to the CTR.
   ```assembly
   mtctr Rx  \(\text{equivalent to: } \text{mtspr } 9, Rx\)
   ```

### E.10 Miscellaneous Mnemonics

#### No-op

Many Power ISA instructions can be coded in a way such that, effectively, no operation is performed. An extended mnemonic is provided for the preferred form of no-op. If an implementation performs any type of run-time optimization related to no-ops, the preferred form is the no-op that will trigger this.

```assembly
nop  \(\text{equivalent to: } \text{ori } 0, 0, 0\)
```

For some uses of a no-op instruction, optimizations related to no-ops, such as removal from the execution stream, are not desirable. An extended mnemonic is provided for the executed form of no-op. This form of no-op will still consume execution resources.

```assembly
xnop  \(\text{equivalent to: } \text{xori } 0, 0, 0\)
```

#### Load Immediate

The `addi` and `addis` instructions can be used to load an immediate value into a register. Extended mnemonics are provided to convey the idea that no addition is being performed but merely data movement (from the immediate field of the instruction to a register).

Load a 16-bit signed immediate value into register Rx.

```assembly
li Rx, value  \(\text{equivalent to: } \text{addi } Rx, 0, \text{value}\)
```

Load a 16-bit signed immediate value, shifted left by 16 bits, into register Rx.

```assembly
lis Rx, value  \(\text{equivalent to: } \text{addis } Rx, 0, \text{value}\)
```
**Load Address**

This mnemonic permits computing the value of a base-displacement operand, using the `addi` instruction which normally requires separate register and immediate operands.

\[
\text{la} \quad Rx,D(Ry) \quad \text{(equivalent to:} \quad \text{addi} \quad Rx,Ry,D) \\
\]

The `la` mnemonic is useful for obtaining the address of a variable specified by name, allowing the Assembler to supply the base register number and compute the displacement. If the variable v is located at offset Dv bytes from the address in register Rv, and the Assembler has been told to use register Rv as a base for references to the data structure containing v, then the following line causes the address of v to be loaded into register Rx.

\[
\text{la} \quad Rx,v \quad \text{(equivalent to:} \quad \text{addi} \quad Rx,Rv,Dv) \\
\]

**Move Register**

Several Power ISA instructions can be coded in a way such that they simply copy the contents of one register to another. An extended mnemonic is provided to convey the idea that no computation is being performed but merely data movement (from one register to another).

The following instruction copies the contents of register Ry to register Rx. This mnemonic can be coded with a final "." to cause the Rc bit to be set in the underlying instruction.

\[
\text{mr} \quad Rx,Ry \quad \text{(equivalent to:} \quad \text{or} \quad Rx,Ry,Ry) \\
\]

**Complement Register**

Several Power ISA instructions can be coded in a way such that they complement the contents of one register and place the result into another register. An extended mnemonic is provided that allows this operation to be coded easily.

The following instruction complements the contents of register Ry and places the result into register Rx. This mnemonic can be coded with a final "." to cause the Rc bit to be set in the underlying instruction.

\[
\text{not} \quad Rx,Ry \quad \text{(equivalent to:} \quad \text{nor} \quad Rx,Ry,Ry) \\
\]

**Move To/From Condition Register**

This mnemonic permits copying the contents of the low-order 32 bits of a GPR to the Condition Register, using the same style as the `mfcr` instruction.

\[
\text{mtcr} \quad Rx \quad \text{(equivalent to:} \quad \text{mtcrf} \quad 0xFF,Rx) \\
\]

The following instructions may generate either the (old) `mtcrf` or `mfcr` instructions or the (new) `mtocrf` or `mfocrf` instruction, respectively, depending on the target machine type assembler parameter.

\[
\text{mtcrf} \quad FXM,Rx \\
\text{mfcr} \quad Rx \\
\]

All three extended mnemonics in this subsection are being phased out. In future assemblers the form "mtcr Rx" may not exist, and the `mtcrf` and `mfcr` mnemonics may generate the old form instructions (with bit 11 = 0) regardless of the target machine type assembler parameter, or may cease to exist.
Appendix F. Programming Examples

F.1 Multiple-Precision Shifts

This section gives examples of how multiple-precision shifts can be programmed.

A multiple-precision shift is defined to be a shift of an N-doubleword quantity (64-bit mode) or an N-word quantity (32-bit mode), where N>1. The quantity to be shifted is contained in N registers. The shift amount is specified either by an immediate value in the instruction, or by a value in a register.

The examples shown below distinguish between the cases N=2 and N>2. If N=2, the shift amount may be in the range 0 through 127 (64-bit mode) or 0 through 63 (32-bit mode), which are the maximum ranges supported by the Shift instructions used. However if N>2, the shift amount must be in the range 0 through 63 (64-bit mode) or 0 through 31 (32-bit mode), in order for the examples to yield the desired result. The specific instance shown for N>2 is N=3; extending those code sequences to larger N is straightforward, as is reducing them to the case N=2 when the more stringent restriction on shift amount is met. For shifts with immediate shift amounts only the case N=3 is shown, because the more stringent restriction on shift amount is always met.

In the examples it is assumed that GPRs 2 and 3 (and 4) contain the quantity to be shifted, and that the result is to be placed into the same registers, except for the immediate left shifts in 64-bit mode for which the result is placed into GPRs 3, 4, and 5. In all cases, for both input and result, the lowest-numbered register contains the highest-order part of the data and highest-numbered register contains the lowest-order part. For non-immediate shifts, the shift amount is assumed to be in GPR 6. For immediate shifts, the shift amount is assumed to be greater than 0. GPRs 30 and 31 are used as scratch registers.

For N>2, the number of instructions required is 2N–1 (immediate shifts) or 3N–1 (non-immediate shifts).
Multiple-precision shifts in 64-bit mode [Category: 64-Bit]

**Shift Left Immediate, N = 3 (shift amnt < 64)**
- `rdicr r5,r4,sh,63-sh`

F.2 Floating-Point Conversions [Category: Floating-Point]

This section gives examples of how the Floating-Point Conversion instructions can be used to perform various conversions.

Warning: Some of the examples use the fsel instruction. Care must be taken in using fsel if IEEE compatibility is required, or if the values being tested can be NaNs or infinities; see Section F.3.4, “Notes” on page 730.

F.2.1 Conversion from Floating-Point Number to Floating-Point Integer

The full convert to floating-point integer function can be implemented with the sequence shown below, assuming the floating-point value to be converted is in FPR 1 and the result is returned in FPR 3.

\[
\begin{align*}
\text{mtfsb0} & \ 23 \quad \text{#clear VXCVI} \\
fctid[z] & \ f3,f1 \quad \text{#convert to fx int} \\
fctid & \ f3,f3 \quad \text{#convert back again} \\
mcrfs & \ 7,5 \quad \text{#VXCVI to CR} \\
bf & \ 31,8 \quad \text{#skip if VXCVI was 0} \\
fmr & \ f3,f1 \quad \text{#input was fp int}
\end{align*}
\]

F.2.2 Conversion from Floating-Point Number to Signed Fixed-Point Integer Doubleword

The full convert to signed fixed-point integer doubleword function can be implemented with the sequence shown below, assuming the floating-point value to be converted is in FPR 1, the value 0 is in FPR 0, the value \(2^{64} - 2^{2048}\) is in FPR 3, the value \(2^{63}\) is in FPR 4 and GPR 4, the result is returned in GPR 3, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space.

\[
\begin{align*}
\text{fsel} & \ f2,f1,f1,f0 \quad \text{#use 0 if < 0} \\
\text{fsub} & \ f5,f3,f1 \quad \text{#use max if > max} \\
\text{fsel} & \ f2,f5,f2,f3 \\
\text{fcmpu} & \ cr2,f2,f4 \quad \text{#subtract } 2^{63} \\
\text{fctid[z]} & \ f2,f2 \quad \text{#use diff if }\geq 2^{63} \\
\text{stfd} & \ f2,\text{disp}(\text{r1}) \quad \text{#store float} \\
\text{ld} & \ r3,\text{disp}(\text{r1}) \quad \text{#load dword} \\
\text{blt} & \ cr2,8 \quad \text{#add } 2^{63} \text{ if input} \\
\text{add} & \ r3,r3,r4 \quad \text{# was }\geq 2^{63}
\end{align*}
\]

F.2.3 Conversion from Floating-Point Number to Unsigned Fixed-Point Integer Doubleword

The full convert to unsigned fixed-point integer doubleword function can be implemented with the sequence shown below, assuming the floating-point value to be converted is in FPR 1, the value 0 is in FPR 0, the value \(2^{64} - 2^{2048}\) is in FPR 3, the value \(2^{63}\) is in FPR 4 and GPR 4, the result is returned in GPR 3, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space.

\[
\begin{align*}
\text{fsel} & \ f2,f1,f1,f0 \quad \text{#use 0 if < 0} \\
\text{fsel} & \ f5,f3,f1 \quad \text{#use max if > max} \\
\text{fsel} & \ f2,f5,f2,f3 \\
\text{fsel} & \ f5,f2,f4 \quad \text{#subtract } 2^{63} \\
\text{fctid[z]} & \ f2,f2 \quad \text{#convert to fx int} \\
\text{stfd} & \ f2,\text{disp}(\text{r1}) \quad \text{#store float} \\
\text{ld} & \ r3,\text{disp}(\text{r1}) \quad \text{#load dword} \\
\text{blt} & \ cr2,8 \quad \text{#add } 2^{63} \text{ if input} \\
\text{add} & \ r3,r3,r4 \quad \text{# was }\geq 2^{63}
\end{align*}
\]

F.2.4 Conversion from Floating-Point Number to Signed Fixed-Point Integer Word

The full convert to signed fixed-point integer word function can be implemented with the sequence shown below, assuming the floating-point value to be converted is in FPR 1, the result is returned in GPR 3, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space.

\[
\begin{align*}
\text{fctiw[z]} & \ f2,f1 \quad \text{#convert to fx int} \\
\text{stfd} & \ f2,\text{disp}(\text{r1}) \quad \text{#store float} \\
\text{lwa} & \ r3,\text{disp}+4(\text{r1}) \quad \text{#load word algebraic}
\end{align*}
\]
F.2.5 Conversion from Floating-Point Number to Unsigned Fixed-Point Integer Word

The full convert to unsigned fixed-point integer word function can be implemented with the sequence shown below, assuming the floating-point value to be converted is in FPR 1, the value 0 is in FPR 0, the value $2^{32} - 1$ is in FPR 3, and the result is returned in GPR 3, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space.

```assembly
fsel f2,f1,f0,f0 # use 0 if < 0
fsub f4,f3,f1 # use max if > max
fsel f2,f4,f2,f3
fctid[f] f2,f2 # convert to fx int
stfd f2,disp(r1) # store float
```

An alternative, shorter, sequence can be used if rounding according to FSCPR is desired and FPSCR specifies Round toward +Infinity or Round toward -Infinity, or if it is acceptable for the rounded answer to be either of the two representable floating-point integers nearest to the given fixed-point integer. In this case the full convert from unsigned fixed-point integer doubleword function can be implemented with the sequence shown below, assuming the value $2^{64}$ is in FPR 2.

```assembly
std r3,disp(r1) # store dword
lfd f1,disp(r1) # load float
fcfid f1,f1 # convert to fp int
```

F.2.6 Conversion from Signed Fixed-Point Integer Doubleword to Floating-Point Number

The full convert from signed fixed-point integer doubleword function, using the rounding mode specified by FPSCR can be implemented with the sequence shown below, assuming the fixed-point value to be converted is in GPR 3, the result is returned in FPR 1, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space.

```assembly
std r3,disp(r1) # store dword
lfd f1,disp(r1) # load float
fcfid f1,f1 # convert to fp int
```

F.2.7 Conversion from Unsigned Fixed-Point Integer Doubleword to Floating-Point Number

The full convert from unsigned fixed-point integer doubleword function, using the rounding mode specified by FPSCR, can be implemented with the sequence shown below, assuming the fixed-point value to be converted is in GPR 3, the value $2^{32}$ is in FPR 4, and the result is returned in FPR 1, and two doublewords at displacement “disp” from the address in GPR 1 can be used as scratch space.

```assembly
rldicl r2,r3,32,32 # isolate high half
rldicl r0,r3,0,32 # isolate low half
std r2,disp(r1) # store dword both
std r0,disp+8(r1)
lfd f2,disp(r1) # load float both
lfd f1,disp+8(r1)
fcfid f2,f2 # convert each half to
fcfid f1,f1 # fp int (exact result)
fmadd f1,f4,f2,f1 # \((2^{32})\times high + low\)
```

F.2.8 Conversion from Signed Fixed-Point Integer Word to Floating-Point Number

The full convert from signed fixed-point integer word function can be implemented with the sequence shown below, assuming the fixed-point value to be converted is in GPR 3, the result is returned in FPR 1, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space. (The result is exact.)

```assembly
extsw r3,r3 # extend sign
std r3,disp(r1) # store dword
lfd f1,disp(r1) # load float
fcfid f1,f1 # convert to fp int
```

The following sequence can be used, assuming a word at the address in GPR 1 + GPR 2 can be used as scratch space.

```assembly
stwx r3,r1,r2 # store word
lfiwax f1,r1,r2 # load float
fcfid f1,f1 # convert to fp int
```

F.2.9 Conversion from Unsigned Fixed-Point Integer Word to Floating-Point Number

The full convert from unsigned fixed-point integer word function can be implemented with the sequence shown below, assuming the fixed-point value to be converted is in GPR 3, the result is returned in FPR 1, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space. (The result is exact.)

```assembly
rldicl r0,r3,0,32 # zero-extend
std r0,disp(r1) # store dword
lfd f1,disp(r1) # load float
fcfid f1,f1 # convert to fp int
```
### F.2.10 Unsigned Single-Precision BCD Arithmetic

The `addg6s` instruction can be used to add or subtract two BCD operands. In these examples it is assumed that `r0` contains `0x666...666`. (BCD data formats are described in Section 6.3 of Book I.)

Addition of the unsigned BCD operand in register `RA` to the unsigned BCD operand in register `RB` can be accomplished as follows.

```
add r1,RA,r0
add r2,r1,RB
addg6s RT,r1,RB # RT = RA + BCD RB
```

Subtraction of the unsigned BCD operand in register `RA` from the unsigned BCD operand in register `RB` can be accomplished as follows. (In this example it is assumed that `RB` is not register 0.)

```
addi r1,RB,1
nor r2,RA,RA  # one's complement of RA
add r3,r1,r2
addg6s RT,r1,r2 # RT = RA - BCD RB
```

Additional instructions are needed to handle signed BCD operands, and BCD operands that occupy more than one register (e.g., unsigned BCD operands that have more than 16 decimal digits).

### F.2.11 Signed Single-Precision BCD Arithmetic

Addition of the signed 15-digit BCD operand in register `RA` to the signed BCD operand in register `RB` can be accomplished as follows. If the signs of operands are different, then the operand of smaller magnitude is subtracted from the operand of larger magnitude and the sign of the larger operand is preserved; otherwise the operands are added and the sign is preserved.

The sign code is in the low order 4 bits of the operands and uses one of the standard encodings. (See Section 6.3 of Book I for a description of BCD and sign encodings.) This example assumes preferred sign option 1 (0b1100 is plus and 0b1101 is minus). For preferred sign option 2 (0b1111 is plus and 0b1101 is minus), replace the `xori` after the "SignedSub" label with "`xori RA,RA,1".

```
xori RA,RA,1
```

SignedAdd:
```
xor r5,RA,RB
andi. r5,r5,15  # compare sign codes
cmpld cr1,RA,RB  # compare magnitudes
beq cr0,samesign
bl cr1,EminusA
```

# set up for RT = RA - BCD RB
```
nor r9,RB,RB    # one's complement of RB
addi r10,RA,16 # generate the carry in
b submag
```

EminusA:
```
# set up for RT = RB - BCD RA
nor r9,RA,RA    # one's complement of RA
addi r10,RB,16 # generate the carry in
```

submag:
```
    rldicr r9,RA,0,59  # remove the sign code
add     r8,RA,0
addg6s  RT,RA,0     # sign position
subf    RT,RT,r8    # RT = RB - BCD RA
b       done
```

samesign:
```
    rldicr r8,RB,0,59  # remove the sign code
add     r10,RA,11
add     r9,RB,8
addg6s  RT,RB       # add 6's
subf    RT,RT,r9    # RT = RA + BCD RB
```

done:

### F.2.12 Unsigned Extended-Precision BCD Arithmetic

Multiple precision BCD arithmetic requires additional code to add/subtract higher order digits and handle the carry between 16 digit groups. For example, the following sequence implements a 32-digit BCD add. In this example the contents of register `R3` concatenated with the contents of `R4` represent the first 32-digit operand and the contents of register `R5` concatenated with the contents of `R6` represents the second operand. The contents of register `R3` concatenated with the contents of register `R4` represents the result.

(In this example `r0` contains `0x6666 6666 6666 6666`.)

```
    add r10,R4,r0
    addc r9,R10,R6  # generate the carry
    addg6s R4,R10,R6 # RT1 = RA1 + BCD RB1
```

```
    rldicr r8,RB,0,59  # remove the sign code
add     r10,RA,11
add     r9,RB,8
addg6s  RT,RB       # add 6's
subf    RT,RT,r9    # RT = RA + BCD RB0
```

Preserving the appropriate sign code is accomplished by zeroing the sign code of the other operand before performing a 16 digit BCD addition/subtraction. Other addends (ones complement or 6's) must leave the sign code position as zero.

(In this example `r11` contains `0x6666 6666 6666 6666`.)

SignedSub:
```
xori RA,RA,1
```

```
add r10,R4,r0
addc r9,R10,R6  # generate the carry
addg6s R4,R10,R6 # RT1 = RA1 + BCD RB1
```

```
addze R5,R5      # propagate the carry
add r10,R3,r0
add r9,R10,R5
addg6s R3,R10,R5 # RT0 = RA0 + BCD RB0
```

```
```
Note that an extra instruction (\textit{addze}) is required to propagate the carry so that the same value is used in the subsequent \textit{add} and \textit{addg6s}.

The following sequence implements a 32-digit BCD subtraction. In this example the first operand in R3 and R4 is subtracted from the 2nd operand in R5 and R6. The result is in R3 and R4.

\begin{verbatim}
addi r10,R6,1
nor r9,R4,R4  # one's complement of RAO
addc r8,r10,r9 # Generate the carry
addg6s R4,r10,r9
subf R4,R4,r8 # RT1 = RB1 - BCD RA1
addze r10,R5 # propagate the carry
nor r9,R3,R3  # one's complement of RAO
add r8,r10,r2
addg6s R3,r10,r9
subf R3,R3,r8 # RT0 = RB0 - BCD RA0
\end{verbatim}
F.3 Floating-Point Selection [Category: Floating-Point]

This section gives examples of how the `Floating Select` instruction can be used to implement floating-point minimum and maximum functions, and certain simple forms of if-then-else constructions, without branching.

The examples show program fragments in an imaginary, C-like, high-level programming language, and the corresponding program fragment using `fsel` and other Power ISA instructions. In the examples, a, b, x, y, and z are floating-point variables, which are assumed to be in FPRs fa, fb, fx, fy, and fz. FPR fs is assumed to be available for scratch space.

Additional examples can be found in Section F.2, “Floating-Point Conversions [Category: Floating-Point]” on page 726.

Warning: Care must be taken in using `fsel` if IEEE compatibility is required, or if the values being tested can be NaNs or infinities; see Section F.3.4.

F.3.1 Comparison to Zero

F.3.4 Notes

The following Notes apply to the preceding examples and to the corresponding cases using the other three arithmetic relations (,<, ≤, and ≠). They should also be considered when any other use of `fsel` is contemplated.

In these Notes, the “optimized program” is the Power ISA program shown, and the “unoptimized program” (not shown) is the corresponding Power ISA program that uses `fcmpu` and `Branch Conditional` instructions instead of `fsel`.

1. The unoptimized program affects the VXSNAN bit of the FPSCR, and therefore may cause the system error handler to be invoked if the corresponding exception is enabled, while the optimized program does not affect this bit. This property of the optimized program is incompatible with the IEEE standard.

2. The optimized program gives the incorrect result if a is a NaN.

3. The optimized program gives the incorrect result if a and/or b is a NaN (except that it may give the correct result in some cases for the minimum and maximum functions, depending on how those functions are defined to operate on NaNs).

4. The optimized program gives the incorrect result if a and b are infinities of the same sign. (Here it is assumed that Invalid Operation Exceptions are disabled, in which case the result of the subtraction is a NaN. The analysis is more complicated if Invalid Operation Exceptions are enabled, because in that case the target register of the subtraction is unchanged.)

5. The optimized program affects the OX, UX, XX, and VXISI bits of the FPSCR, and therefore may cause the system error handler to be invoked if the corresponding exceptions are enabled, while the unoptimized program does not affect these bits. This property of the optimized program is incompatible with the IEEE standard.
F.4 Vector Unaligned Storage Operations [Category: Vector]

F.4.1 Loading a Unaligned Quadword Using Permute from Big-Endian Storage

The following sequence of instructions copies the unaligned quadword storage operand into VRT.

```
# Assumptions:
# Rb != 0 and contents of Rb = 0xB
lvx    Vhi,0,Rb  # load MSQ
lvsl   Vp,0,Rb   # set permute control vector
addi   Rb,Rb,16 # address of LSQ
lvx    Vlo,0,Rb  # load LSQ
perm   Vt,Vhi,Vlo,Vp # align the data
```
Book II:

Power ISA Virtual Environment Architecture
Chapter 1. Storage Model

1.1 Definitions

The following definitions, in addition to those specified in Book I, are used in this Book. In these definitions, “Load instruction” includes the Cache Management and other instructions that are stated in the instruction descriptions to be “treated as a Load”, and similarly for “Store instruction”.

- system
  A combination of processors, storage, and associated mechanisms that is capable of executing programs. Sometimes the reference to system includes services provided by the privileged software.

- main storage
  The level of storage hierarchy in which all storage state is visible to all processors and mechanisms in the system.

- primary cache
  The level of cache closest to the processor.

- secondary cache
  After the primary cache, the next closest level of cache to the processor.

- instruction storage
  The view of storage as seen by the mechanism that fetches instructions.

- data storage
  The view of storage as seen by a Load or Store instruction.

- program order
  The execution of instructions in the order required by the sequential execution model. (See Section 2.2 of Book I.) A dcbz instruction that modifies storage which contains instructions has the same effect with respect to the sequential execution model as a Store instruction as described there. An additional exception to the sequential execution model beyond those described in Book I is caused by transaction failure (see Section 5.3.3).

- storage location
  A contiguous sequence of one or more bytes in storage. When used in association with a specific instruction or the instruction fetching mechanism, the length of the sequence of one or more bytes is typically implied by the operation. In other uses, it may refer more abstractly to a group of bytes which share common storage attributes.

- storage access
  An access to a storage location. There are three (mutually exclusive) kinds of storage access.

  - data access
    An access to the storage location specified by a Load or Store instruction, or, if the access is performed “out-of-order” (see Section 5.5 of Book III-S and Section 6.5 of Book III-E), an access to a storage location as if it were the storage location specified by a Load or Store instruction.

  - instruction fetch
    An access for the purpose of fetching an instruction.

  - implicit access
    An access by the processor for the purpose of address translation or reference and change recording (see Book III-S).

- caused by, associated with

  - caused by
    A storage access is said to be caused by an instruction if the instruction is a Load or Store and the access (data access) is to the storage location specified by the instruction.

  - associated with
    A storage access is said to be associated with an instruction if the access is for the purpose of fetching the instruction (instruction fetch), or is a data access caused by the instruction, or is an implicit access that occurs as a side effect of fetching or executing the instruction.
prefetched instructions
Instructions for which a copy of the instruction has been fetched from instruction storage, but the instruction has not yet been executed.

uniprocessor
A system that contains one processor.

multiprocessor
A system that contains two or more processors.

shared storage multiprocessor
A multiprocessor that contains some common storage, which all the processors in the system can access.

performed
A load or instruction fetch by a processor or mechanism (P1) is performed with respect to any processor or mechanism (P2) when the value to be returned by the load or instruction fetch can no longer be changed by a store by P2. A store by P1 is performed with respect to P2 when a load by P2 from the location accessed by the store will return the value stored (or a value stored subsequently). An instruction cache block invalidation by P1 is performed with respect to P2 when an instruction fetch by P2 will not be satisfied from the copy of the block that existed in its instruction cache when the instruction causing the invalidation was executed, and similarly for a data cache block invalidation.

The preceding definitions apply regardless of whether P1 and P2 are the same entity.

page (virtual page)
$2^n$ contiguous bytes of storage aligned such that the effective address of the first byte in the page is an integral multiple of the page size for which protection and control attributes are independently specifiable and for which reference and change status <$S$> are independently recorded.

block
The aligned unit of storage operated on by the Cache Management instructions. The size of an instruction cache block may differ from the size of a data cache block, and both sizes may vary between implementations. The maximum block size is equal to the minimum page size.

aligned storage access
A load or store is aligned if the address of the target storage location is a multiple of the size of the transfer effected by the instruction.

aggregate store
The set of stores caused by a successful transaction, which are performed as an atomic unit.

1.2 Introduction

The Power ISA User Instruction Set Architecture, discussed in Book I, defines storage as a linear array of bytes indexed from 0 to a maximum of $2^{64}$-1. Each byte is identified by its index, called its address, and each byte contains a value. This information is sufficient to allow the programming of applications that require no special features of any particular system environment. The Power ISA Virtual Environment Architecture, described herein, expands this simple storage model to include caches, virtual storage, and shared storage multiprocessors. The Power ISA Virtual Environment Architecture, in conjunction with services based on the Power ISA Operating Environment Architecture (see Book III) and provided by the operating system, permits explicit control of this expanded storage model. A simple model for sequential execution allows at most one storage access to be performed at a time and requires that all storage accesses appear to be performed in program order. In contrast to this simple model, the Power ISA specifies a relaxed model of storage consistency. In a multiprocessor system that allows multiple copies of a storage location, aggressive implementations of the architecture can permit intervals of time during which different copies of a storage location have different values. This chapter describes features of the Power ISA that enable programmers to write correct programs for this storage model.

1.3 Virtual Storage

The Power ISA system implements a virtual storage model for applications. This means that a combination of hardware and software can present a storage model that allows applications to exist within a “virtual” address space larger than either the effective address space or the real address space.

Each program can access $2^{64}$ bytes of “effective address” (EA) space, subject to limitations imposed by the operating system. In a typical Power ISA system, each program's EA space is a subset of a larger “virtual address” (VA) space managed by the operating system. Each effective address is translated to a real address (i.e., to an address of a byte in real storage or on an I/O device) before being used to access storage. The hardware accomplishes this, using the address translation mechanism described in Book III. The operating system manages the real (physical) storage resources of the system, by setting up the tables and other information used by the hardware address translation mechanism.

In general, real storage may not be large enough to map all the virtual pages used by the currently active applications. With support provided by hardware, the
operating system can attempt to use the available real pages to map a sufficient set of virtual pages of the applications. If a sufficient set is maintained, "paging" activity is minimized. If not, performance degradation is likely.

The operating system can support restricted access to virtual pages (including read/write, read only, and no access; see Book III), based on system standards (e.g., virtual pages (including read/write, read only, and no access); see Book III), based on system standards (e.g., program code might be read only) and application requests.

1.4 Single-Copy Atomicity

An access is single-copy atomic, or simply atomic, if it is always performed in its entirety with no visible fragmentation. Atomic accesses are thus serialized: each happens in its entirety in some order, even when that order is not specified in the program or enforced between processors.

Vector storage accesses are not guaranteed to be atomic. The following other types of single-register accesses are always atomic:
- byte accesses (all bytes are aligned on byte boundaries)
- halfword accesses aligned on halfword boundaries
- word accesses aligned on word boundaries
- doubleword accesses aligned on doubleword boundaries (64-bit implementations only; see Section 1.2 of Book III-E)<E>

No other accesses are guaranteed to be atomic. For example, the access caused by the following instructions is not guaranteed to be atomic.
- any Load or Store instruction for which the operand is unaligned
- imw, stmw, lwisi, lswi, stswi, stswx
- lfdp, lfdpx, stfdp, stfdpx
- any Cache Management instruction

An access that is not atomic is performed as a set of smaller disjoint atomic accesses. In general, the number and alignment of these accesses are implementation-dependent, as is the relative order in which they are performed. The only exception to the preceding rule is that, for lfdp, lfdpx, stfdp, and stfdpx, if the access is aligned on a doubleword boundary, it is performed as a pair of disjoint atomic doubleword accesses.

The results for several combinations of loads and stores to the same or overlapping locations are described below.
1. When two processors execute atomic stores to locations that do not overlap, and no other stores are performed to those locations, the contents of those locations are the same as if the two stores were performed by a single processor.
2. When two processors execute atomic stores to the same storage location, and no other store is performed to that location, the contents of that location are the result stored by one of the processors.
3. When two processors execute stores that have the same target location and are not guaranteed to be atomic, and no other store is performed to that location, the result is some combination of the bytes stored by both processors.
4. When two processors execute stores to overlapping locations, and no other store is performed to those locations, the result is some combination of the bytes stored by the processors to the overlapping bytes. The portions of the locations that do not overlap contain the bytes stored by the processor storing to the location.
5. When a processor executes an atomic store to a location, a second processor executes an atomic load from that location, and no other store is performed to that location, the value returned by the load is the contents of the location before the store or the contents of the location after the store.
6. When a load and a store with the same target location can be executed simultaneously, and no other store is performed to that location, the value returned by the load is some combination of the contents of the location before the store and the contents of the location after the store.

1.5 Cache Model

A cache model in which there is one cache for instructions and another cache for data is called a "Harvard-style" cache. This is the model assumed by the Power ISA, e.g., in the descriptions of the Cache Management instructions in Section 4.3. Alternative cache models may be implemented (e.g., a "combined cache" model, in which a single cache is used for both instructions and data, or a model in which there are several levels of caches), but they support the programming model implied by a Harvard-style cache.

The processor is not required to maintain copies of storage locations in the instruction cache consistent with modifications to those storage locations (e.g., modifications caused by Store instructions).

A location in the data cache is considered to be modified in that cache if the location has been modified (e.g., by a Store instruction) and the modified data have not been written to main storage.

Cache Management instructions are provided so that programs can manage the caches when needed. For example, program management of the caches is needed when a program generates or modifies code that will be executed (i.e., when the program modifies...
data in storage and then attempts to execute the modified data as instructions. The Cache Management instructions are also useful in optimizing the use of memory bandwidth in such applications as graphics and numerically intensive computing. The functions performed by these instructions depend on the storage control attributes associated with the specified storage location (see Section 1.6, “Storage Control Attributes”).

The Cache Management instructions allow the program to do the following.

- invalidate the copy of storage in an instruction cache block (icbi)
- provide a hint that an instruction will probably soon be accessed from a specified instruction cache block (icbi)
- provide a hint that the program will probably soon access a specified data cache block (dcbt, dcbtst)
- <E> allocate a data cache block and set the contents of that block to zeros, but perform no operation if no write access is allowed to the data cache block (dcbf)
- set the contents of a data cache block to zeros (dcbz)
- copy the contents of a modified data cache block to main storage (dcbs)
- copy the contents of a modified data cache block to main storage and make the copy of the block in the data cache invalid (dcbf or dcbt)

1.6 Storage Control Attributes

Some operating systems may provide a means to allow programs to specify the storage control attributes described in this section. Because the support provided for these attributes by the operating system may vary between systems, the details of the specific system being used must be known before these attributes can be used.

Storage control attributes are associated with units of storage that are multiples of the page size. Each storage access is performed according to the storage control attributes of the specified storage location, as described below. The storage control attributes are the following.

- Write Through Required
- Caching Inhibited
- Memory Coherence Required
- Guarded
- Endianness <E>
- Strong Access Order [Category: SAO]

These attributes have meaning only when an effective address is translated by the processor performing the storage access.

<E> Additional storage control attributes may be defined for some implementations. See Section 6.8 of Book III-E for additional information.

---

Programming Note

The Write Through Required and Caching Inhibited attributes are mutually exclusive because, as described below, the Write Through Required attribute permits the storage location to be in the data cache while the Caching Inhibited attribute does not.

Storage that is Write Through Required or Caching Inhibited is not intended to be used for general-purpose programming. For example, the lbarx, lbarx, lbarx, ldarx, lqarx, stbcx, sthcx, stwcx, stdcx, and stqcx instructions may cause the system data storage error handler to be invoked if they specify a location in storage having either of these attributes.

In the remainder of this section, “Load” instruction includes the Cache Management and other instructions that are stated in the instruction descriptions to be “treated as a Load” unless they are explicitly excluded, and similarly for “Store” instruction.

1.6.1 Write Through Required

A store to a Write Through Required storage location is performed in main storage. A Store instruction that specifies a location in Write Through Required storage may cause additional locations in main storage to be accessed. If a copy of the block containing the specified location is retained in the data cache, the store is also performed in the data cache. The store does not cause the block to be considered to be modified in the data cache.

In general, accesses caused by separate Store instructions that specify locations in Write Through Required storage may be combined into one access. Such combining does not occur if the Store instructions are separated by a sync, eieio <S>, or mbar <E> instruction.

1.6.2 Caching Inhibited

An access to a Caching Inhibited storage location is performed in main storage. A Load instruction that specifies a location in Caching Inhibited storage may cause additional locations in main storage to be accessed unless the specified location is also Guarded. An instruction fetch from Caching Inhibited storage may cause additional words in main storage to be accessed. No copy of the accessed locations is placed into the caches.

In general, non-overlapping accesses caused by separate Load instructions that specify locations in Caching Inhibited storage may be combined into one access, as may non-overlapping accesses caused by separate Store instructions that specify locations in Caching Inhibited storage. Such combining does not occur if the Load or Store instructions are separated by a sync or mbar <E> instruction. Combining may also occur.
among such accesses from multiple processors that share a common memory interface. No combining occurs if the storage is also Guarded.

Programming Note

None of the memory barrier instructions prevent the combining of accesses from different processors. The Guarded storage attribute must be used in combination with Caching Inhibited to prevent such combining.

1.6.3 Memory Coherence Required [Category: Memory Coherence]

An access to a Memory Coherence Required storage location is performed coherently, as follows.

Memory coherence refers to the ordering of stores to a single location. Atomic stores to a given location are coherent if they are serialized in some order, and no processor or mechanism is able to observe any subset of those stores as occurring in a conflicting order. This serialization order is an abstract sequence of values; the physical storage location need not assume each of the values written to it. For example, a processor may update a location several times before the value is written to physical storage. The result of a store operation is not available to every processor or mechanism at the same instant, and it may be that a processor or mechanism observes only some of the values that are written to a location. However, when a location is accessed atomically and coherently by all processors and mechanisms, the sequence of values loaded from the location by any processor or mechanism during any interval of time forms a subsequence of the sequence of values that the location logically held during that interval. That is, a processor or mechanism can never load a “newer” value first and then, later, load an “older” value.

Memory coherence is managed in blocks called coherence blocks. Their size is implementation-dependent, but is larger than a word and is usually the size of a cache block.

For storage that is not Memory Coherence Required, software must explicitly manage memory coherence to the extent required by program correctness. The operations required to do this may be system-dependent.

Because the Memory Coherence Required attribute for a given storage location is of little use unless all processors that access the location do so coherently, in statements about Memory Coherence Required storage elsewhere in this document it is generally assumed that the storage has the Memory Coherence Required attribute for all processors that access it.

Programming Note

Operating systems that allow programs to request that storage not be Memory Coherence Required should provide services to assist in managing memory coherence for such storage, including all system-dependent aspects thereof.

In most systems the default is that all storage is Memory Coherence Required. For some applications in some systems, software management of coherence may yield better performance. In such cases, a program can request that a given unit of storage not be Memory Coherence Required, and can manage the coherence of that storage by using the sync instruction, the Cache Management instructions, and services provided by the operating system.

1.6.4 Guarded

A data access to a Guarded storage location is performed only if either (a) the access is caused by an instruction that is known to be required by the sequential execution model, or (b) the access is a load and the storage location is already in a cache. If the storage is also Caching Inhibited, only the storage location specified by the instruction is accessed; otherwise any storage location in the cache block containing the specified storage location may be accessed.

For the Server environment, instructions are not fetched from virtual storage that is Guarded. If the instruction addressed by the current instruction address is in such storage, the system instruction storage error handler may be invoked (see Section 6.5.5 of Book III-S).

Programming Note

In some implementations, instructions may be executed before they are known to be required by the sequential execution model. Because the results of instructions executed in this manner are discarded if it is later determined that those instructions would not have been executed in the sequential execution model, this behavior does not affect most programs.

This behavior does affect programs that access storage locations that are not “well-behaved” (e.g., a storage location that represents a control register on an I/O device that, when accessed, causes the device to perform an operation). To avoid unintended results, programs that access such storage locations should request that the storage be Guarded, and should prevent such storage locations from being in a cache (e.g., by requesting that the storage also be Caching Inhibited).
1.6.5 Endianness [Category: Embedded.Little-Endian]

The Endianness storage control attribute specifies the byte ordering (Big-Endian or Little-Endian) that is used when the storage location is accessed; see Section 1.10 of Book I.

1.6.6 Variable Length Encoded (VLE) Instructions

VLE storage is used to store VLE instructions. Instructions fetched from VLE storage are processed as VLE instructions. VLE storage must also be Big-Endian. Instructions fetched from VLE storage that is Little-Endian cause a Byte-ordering exception, and the system instruction storage error handler will be invoked.

The VLE attribute has no effect on data accesses. See Chapter 1 of Book VLE.
1.6.7 Strong Access Order [Category: SAO]

All accesses to storage with the Strong Access Order (SAO) attribute (referred to as SAO storage) will be performed using a set of ordering rules different from that of the weakly consistent model that is described in Section 1.7.1, “Storage Access Ordering”. These rules apply only to accesses that are caused by a Load or a Store, and not to accesses associated with those instructions. Furthermore, these rules do not apply to accesses that are caused by or associated with instructions that are stated in their descriptions to be “treated as a Load” or “treated as a Store.” The details are described below, from the programmer’s point of view. (The processor may deviate from these rules if the programmer cannot detect the deviation.) The SAO attribute is not intended to be used for general purpose programming. It is provided in a manner that is not fully independent of the other storage attributes. Specifically, it is only provided for storage that is Memory Coherence Required, but not Write Through Required, not Caching Inhibited, and not Guarded. See Section 5.8.2.1, “Storage Control Bit Restrictions”, in Book III-S for more details. Accesses to SAO storage are likely to be performed more slowly than similar accesses to non-SAO storage.

The order in which a processor performs storage accesses to SAO storage, the order in which those accesses are performed with respect to other processors and mechanisms, and the order in which those accesses are performed in main storage are the same except in the circumstances described in the following paragraph. The ordering rules for accesses performed by a single processor to SAO storage are as follows.

Stores are performed in program order. When a store accesses data adjacent to that which is accessed by the next store in program order, the two storage accesses may be combined into a single larger access.

Loads are performed in program order. When a load accesses data adjacent to that which is accessed by the next load in program order, the two storage accesses may be combined into a single larger access.

Stores may not be performed before loads which precede them in program order. Loads may be performed before stores which precede them in program order, with the provision that a load which follows a store of the same datum (to the same address) must obtain a value which is no older (in consideration of the possibility of programs on other processors sharing the same storage) than the value stored by the preceding store.

When any given processor loads the datum it just stored, as described above, the load may be performed by the processor before the preceding store has been performed with respect to other processors and mechanisms, and in main storage. This may cause the processor to see its store earlier relative to stores performed by other processors than it is observed by other processors and mechanisms, and than it is performed in memory. A direct consequence of this consideration is that although programs running on each processor will see the same sequence of accesses from any individual processor to SAO storage, each may in general see a different interleaving of the individual sequences. The memory barrier instructions may be used to establish stronger ordering, as described in Section 1.7.1, “Storage Access Ordering”, beginning with the third major bullet.
1.7 Shared Storage

This architecture supports the sharing of storage between programs, between different instances of the same program, and between processors and other mechanisms. It also supports access to a storage location by one or more programs using different effective addresses. All these cases are considered storage sharing. Storage is shared in blocks that are an integral number of pages.

When the same storage location has different effective addresses, the addresses are said to be aliases. Each application can be granted separate access privileges to aliased pages.

1.7.1 Storage Access Ordering

The Power ISA defines two models for the ordering of storage accesses: weakly consistent and strong access ordering. The predominant model is weakly consistent. This model provides an opportunity for improved performance over a model that has stronger consistency rules, but places the responsibility on the program to ensure that ordering or synchronization instructions are properly placed when storage is shared by two or more programs. Implementations which support Category SAO apply a stronger consistency model among accesses to SAO storage. The order between accesses to SAO storage and those performed using the weakly consistent model is characteristic of the weakly consistent model. The following description, through the second major bullet, applies only to the weakly consistent model. The corresponding description for SAO storage is found in Section 1.6.7, “Strong Access Order [Category: SAO]”. The rest of the description following the second bulletted item applies to both models.

The order in which the processor performs storage accesses, the order in which those accesses are performed with respect to another processor or mechanism, and the order in which those accesses are performed in main storage may all be different. Several means of enforcing an ordering of storage accesses are provided to allow programs to share storage with other programs, or with mechanisms such as I/O devices. These means are listed below. The phrase “to the extent required by the associated Memory Coherence Required attributes” refers to the Memory Coherence Required attribute, if any, associated with each access.

- If two Store instructions or two Load instructions specify storage locations that are both Caching Inhibited and Guarded, the corresponding storage accesses are performed in program order with respect to any processor or mechanism.

- If a Load instruction depends on the value returned by a preceding Load instruction (because the value is used to compute the effective address specified by the second Load), the corresponding storage accesses are performed in program order with respect to any processor or mechanism to the extent required by the associated Memory Coherence Required attributes. This applies even if the dependency has no effect on program logic (e.g., the value returned by the first Load is ANDed with zero and then added to the effective address specified by the second Load).

- When a processor (P1) executes a Synchronize, eieio<->, or mbar<-> instruction a memory barrier is created, which orders applicable storage accesses pairwise, as follows. Let A be a set of storage accesses that includes all storage accesses associated with instructions preceding the barrier-creating instruction, and let B be a set of storage accesses that includes all storage accesses associated with instructions following the barrier-creating instruction. For each applicable pair a_i,b_j of storage accesses such that a_i is in A and b_j is in B, the memory barrier ensures that a_i will be performed with respect to any processor or mechanism, to the extent required by the associated Memory Coherence Required attributes, before b_j is performed with respect to that processor or mechanism.

The ordering done by a memory barrier is said to be “cumulative” if it also orders storage accesses that are performed by processors and mechanisms other than P1, as follows.

- A includes all applicable storage accesses by any such processor or mechanism that have been performed with respect to P1 before the memory barrier is created.

- B includes all applicable storage accesses by any such processor or mechanism that are performed after a Load instruction executed by that processor or mechanism has returned the value stored by a store that is in B.

No ordering should be assumed among the storage accesses caused by a single instruction (i.e., by an instruction for which the access is not atomic), even if the accesses are to SAO storage, and no means are provided for controlling that order.
Because stores cannot be performed “out-of-order” (see Book III), if a Store instruction depends on the value returned by a preceding Load instruction (because the value returned by the Load is used to compute either the effective address specified by the Store or the value to be stored), the corresponding storage accesses are performed in program order. The same applies if whether the Store instruction is executed depends on a conditional Branch instruction that in turn depends on the value returned by a preceding Load instruction.

Because an isync instruction prevents the execution of instructions following the isync until instructions preceding the isync have completed, if an isync follows a conditional Branch instruction that depends on the value returned by a preceding Load instruction, the load on which the Branch depends is performed before any loads caused by instructions following the isync. This applies even if the effects of the “dependency” are independent of the value loaded (e.g., the value is compared to itself and the Branch tests the EQ bit in the selected CR field), and even if the branch target is the sequentially next instruction.

With the exception of the cases described above and earlier in this section, data dependencies and control dependencies do not order storage accesses. Examples include the following.

- If a Load instruction specifies the same storage location as a preceding Store instruction and the location is in storage that is not Caching Inhibited, the load may be satisfied from a “store queue” (a buffer into which the processor places stored values before presenting them to the storage sub-system), and not be visible to other processors and mechanisms. A consequence is that if a subsequent Store depends on the value returned by the Load, the two stores need not be performed in program order with respect to other processors and mechanisms.

- Because a Store Conditional instruction may complete before its store has been performed, a conditional Branch instruction that depends on the CR0 value set by a Store Conditional instruction does not order the Store Conditional’s store with respect to storage accesses caused by instructions that follow the Branch.

- Because processors may predict branch target addresses and branch condition resolution, control dependencies (e.g., branches) do not order storage accesses except as described above. For example, when a subroutine returns to its caller the return address may be predicted, with the result that loads caused by instructions at or after the return address may be performed before the load that obtains the return address is performed.

Because processors may implement nonarchitected duplicates of architected resources (e.g., GPRs, CR fields, and the Link Register), resource dependencies (e.g., specification of the same target register for two Load instructions) do not order storage accesses.

Examples of correct uses of dependencies, sync, lwsync, and eieio S to order storage accesses can be found in Appendix B. “Programming Examples for Sharing Storage” on page 829.

Because the storage model is weakly consistent, the sequential execution model as applied to instructions that cause storage accesses guarantees only that those accesses appear to be performed in program order with respect to the processor executing the instructions. For example, an instruction may complete, and subsequent instructions may be executed, before storage accesses caused by the first instruction have been performed. However, for a sequence of atomic accesses to the same storage location, if the location is in storage that is Memory Coherence Required the definition of coherence guarantees that the accesses are performed in program order with respect to any processor or mechanism that accesses the location coherently, and similarly if the location is in storage that is Caching Inhibited.

Because accesses to storage that is Caching Inhibited are performed in main storage, memory barriers and dependencies on Load instructions order such accesses with respect to any processor or mechanism even if the storage is not Memory Coherence Required.
1.7.2 Storage Ordering of I/O Accesses

A “coherence domain” consists of all processors and all interfaces to main storage. Memory reads and writes initiated by mechanisms outside the coherence domain are performed within the coherence domain in the order in which they enter the coherence domain and are performed as coherent accesses.

1.7.3 Atomic Update

The Load And Reserve and Store Conditional instructions together permit atomic update of a shared storage location. There are byte, halfword, word, doubleword, and quadword forms of each of these instructions. Described here is the operation of the word forms lwarx and stwcx; operation of the byte, halfword, dou-
A reservation for a subsequent \texttt{stwcx}. instruction is created.

2. The memory coherence mechanism is notified that a reservation exists for the storage location specified by the \texttt{lwarx}.

The \texttt{stwcx}. instruction is a store to a word-aligned location that is conditioned on the existence of the reservation created by the \texttt{lwarx} and on whether the same storage location is specified by both instructions. To emulate an atomic operation with these instructions, it is necessary that both the \texttt{lwarx} and the \texttt{stwcx}. specify the same storage location.

A \texttt{stwcx}. performs a store to the target storage location only if the storage location specified by the \texttt{lwarx} that established the reservation has not been stored into by another processor or mechanism since the reservation was created. If the storage locations specified by the two instructions differ, the store is not necessarily performed except that if the Store Conditional Page Mobility category is supported and the storage locations are in different naturally aligned blocks of real storage whose size is the smallest real page size supported by the implementation, the store is not performed.

A \texttt{stwcx}. that performs its store is said to “succeed”.

Examples of the use of \texttt{lwarx} and \texttt{stwcx}. are given in Appendix B. “Programming Examples for Sharing Storage” on page 829.

A successful \texttt{stwcx}. to a given location may complete before its store has been performed with respect to other processors and mechanisms. As a result, a subsequent load or \texttt{lwarx} from the given location by another processor may return a “stale” value. However, a subsequent \texttt{lwarx} from the given location by the other processor followed by a successful \texttt{stwcx}. by that processor is guaranteed to have returned the value stored by the first processor’s \texttt{stwcx}. (in the absence of other stores to the given location).

If a \textit{Store Conditional} instruction is used with a preceding \textit{Load And Reserve} instruction that has a different storage operand length (e.g., \texttt{stwcx}. with \texttt{idarx}), the reservation is cleared and it is undefined whether the store is performed.

\begin{center}
\textbf{Programming Note}
\end{center}

The store caused by a successful \texttt{stwcx}. is ordered, by a dependence on the reservation, with respect to the load caused by the \texttt{lwarx} that established the reservation, such that the two storage accesses are performed in program order with respect to any processor or mechanism.

Before reassigning a virtual address to a different real page, privileged software may need to clear all processors’ reservations for the original real page in order to avoid a \textit{Store Conditional} being successful only because the corresponding reservation for the original location is not cleared by a store to the new real page by some other processor or mechanism. This clearing of reservations is unnecessary on processors that support the Store Conditional Page Mobility category.

The Store Conditional Page Mobility category does not provide a mechanism for the \textit{Store Conditional} instruction to detect that a virtual page has been moved to a new real page and back again to the original real page that was accessed by a \textit{Load and Reserve} instruction. Privileged software that moves a virtual page could clear the reservation on the processor it is running on in order to ensure that a \textit{Store Conditional} instruction executed by that processor does not succeed in this case. (The stores that occur naturally as part of moving the virtual page will cause any reservations, held by other processors, in the target real page to be lost.)

\subsection{Reservations}

The ability to emulate an atomic operation using \texttt{lwarx} and \texttt{stwcx}. is based on the conditional behavior of \texttt{stwcx}. the reservation created by \texttt{lwarx}, and the clearing of that reservation if the target storage location is modified by another processor or mechanism before the \texttt{stwcx}. performs its store.

A reservation is held on an aligned unit of real storage called a reservation granule. The size of the reservation granule is $2^n$ bytes, where $n$ is implementation-dependent but is always at least 4 (thus the minimum reservation granule size is a quadword) and, if the Store Conditional Page Mobility category is supported, where $2^n$ is not larger than the smallest real page size supported by the implementation. The reservation granule associated with effective address $EA$ contains the real address to which $EA$ maps. (*real_addr($EA$) in the RTL for the \textit{Load And Reserve} and \textit{Store Conditional} instructions stands for “real address to which $EA$ maps”.) The reservation also has an associated length, which is equal to the storage operand length, in bytes, of the \textit{Load And Reserve} instruction that established the reservation.

A processor has at most one reservation at any time. A reservation is established by executing a \texttt{lbarx}, \texttt{lharx}, \texttt{lwarx}, \texttt{idarx}, or \texttt{iqarx} instruction, as described in item 1 below, and is lost or may be lost, depending on the item, if any of the following occur. Items 1-8 apply only if the relevant access is performed. (For example, an access that would ordinarily be caused by an instruc-
tion might not be performed if the instruction causes the system error handler to be invoked.)

1. The processor holding the reservation executes another `lbarx`, `lharx`, `lwarx`, or `ldarx`: this clears the first reservation and establishes a new one.

2. The processor holding the reservation executes any `stbcx`, `sthcx`, `stwcx`, `stdcx`, or `stqcx`, regardless of whether the specified address matches the address specified by the `lbarx`, `lharx`, `lwarx`, `ldarx`, or `lqarx` that established the reservation, and regardless of whether the storage operand lengths of the two instructions are the same.

3. <TM> Any of the following occurs on the processor holding the reservation.
   a. The transaction state changes (from Non-transactional, Transactional, or Suspended state to one of the other two states; see Section 5.2, "Transactional Memory Facility States"), except in the following cases
      ■ If the change is from Transactional state to Suspended state, the reservation is not lost.
      ■ If the change is from Suspended state to Transactional state, the reservation is not lost if it was established in Transactional state.
      ■ If the change is caused by a `treclaim`, or `trechkpt`, instruction, whether the reservation is lost is undefined.
   b. The transaction nesting depth (see Section 5.4, "Transactional Memory Facility Registers") changes; whether the reservation is lost is undefined. (This item applies only if the processor is in Transactional state both before and after the change.)
   c. The processor is in Suspended state and executes a `Store Conditional` instruction (`stbcx`, `sthcx`, `stwcx`, `stdcx`, or `stqcx`) or a `waitrsv` instruction; the reservation is lost if it was established in Transactional state. In this case the `Store Conditional` instruction's store is not performed, and the `waitrsv` does not wait. (For `Store Conditional`, the reservation is also lost if it was established in Suspended state; see item 2.)

4. Some other processor executes a `Store`, `dcbz`, or `dcbzep`<E> that specifies a location in the same reservation granule.

5. Some other processor executes a `dcbtst`, `dcbtstep`<E>, or `dcbtstls`<E> that specifies a location in the same reservation granule: whether the reservation is lost is undefined. (For a `dcbtst` instruction that specifies a data stream, "location" in the preceding sentence includes all locations in the data stream.)

6. <E> Some other processor executes a `dcbx` that specifies a location in the same reservation granule: the reservation is lost if the instruction causes the target block to be newly established in a data cache or to be modified; otherwise whether the reservation is lost is undefined.

7. <E> Some other processor executes a `dcbi` that specifies a location in the same reservation granule: the reservation may be lost if the instruction is treated as a `Store`.

8. <S> Any processor modifies a Reference or Change bit (see Book III-S) in the same reservation granule: whether the reservation is lost is undefined.

9. Some mechanism other than a processor modifies a storage location in the same reservation granule.

10. An interrupt (see Book III) occurs on the processor holding the reservation: for the Embedded environment, the reservation may be lost if the interrupt is asynchronous. (For the Server environment the reservation is not lost. However, for both environments, system software invoked by interrupts may clear the reservation.)

11. Implementation-specific characteristics of the coherence mechanism cause the reservation to be lost.

---

Virtualized Implementation Note

A reservation may be lost if:

- Software executes a privileged instruction or utilizes a privileged facility
- Software accesses storage not intended for general-purpose programming
- Software executes a Decorated Storage instruction <DS>
- Software accesses a Device Control Register
1.7.3.2 Forward Progress

Forward progress in loops that use \texttt{lwarx} and \texttt{stwcx} is achieved by a cooperative effort among hardware, system software, and application software. The architecture guarantees that when a processor executes a \texttt{lwarx} to obtain a reservation for location X and then a \texttt{stwcx} to store a value to location X, either

1. the \texttt{stwcx} succeeds and the value is written to location X, or
2. the \texttt{stwcx} fails because some other processor or mechanism modified location X, or
3. the \texttt{stwcx} fails because the processor’s reservation was lost for some other reason.

In Cases 1 and 2, the system as a whole makes progress in the sense that some processor successfully modifies location X. Case 3 covers reservation loss required for correct operation of the rest of the system. This includes cancellation caused by some other processor or mechanism writing elsewhere in the reservation granule, cancellation caused by the operating system in managing certain limited resources such as real storage, and cancellation caused by any of the other effects listed in see Section 1.7.3.1.

An implementation may make a forward progress guarantee, defining the conditions under which the system as a whole makes progress. Such a guarantee must specify the possible causes of reservation loss in Case 3. While the architecture alone cannot provide such a guarantee, the characteristics listed in Cases 1 and 2 are necessary conditions for any forward progress guarantee. An implementation and operating system can build on them to provide such a guarantee.
## 1.8 Transactions [Category: Transactional Memory]

A transaction is a group of instructions that collectively have unique storage access behavior intended to facilitate parallel programming. (It is possible to nest transactions within one another. The description in this chapter will ignore nesting because it does not have a significant impact on the properties of the memory model. Nesting and its consequences will be described elsewhere.) Sequences of instructions that are part of the transaction may be interleaved with sequences of Suspended state instructions that are not part of the transaction. A transaction is said to “succeed” or to “fail,” and failure may happen before all of the instructions in the transaction have completed. If the transaction fails, it is as if the instructions that are part of the transaction were never executed. If the transaction succeeds, it appears to execute as an atomic unit as viewed by other processors and mechanisms.

(Although the transaction appears to execute atomically, some knowledge of the inner workings will be necessary to avoid apparent paradoxes in the rest of the model. These details are described below.) The execution of Suspended state sequences have the same effect that the sequence would have in the absence of a transaction, independent of the success or failure of the transaction, including accessing storage according to the weakly consistent storage model or SAO, based on storage attributes. Upon failure, normal execution continues at the failure handler. Except for the rollback of the effects of transactional instructions upon transaction failure, as viewed by the executing thread, the interleaved sequences of Transactional and Suspended state instructions appear to execute according to the sequential execution model. See Chapter 5. “Transactional Memory Facility [Category: Transactional Memory]” on page 795 for more details.

The unique attributes of the storage model for transactions are described below.

Transaction processing does not support the rollback of operations on the reservation mechanism. To prevent this possibility, a reservation is lost as a result of a state change from Transactional to Non-transactional or Non-transactional to Transactional. It is possible to successfully complete an atomic update in Transactional state, though such a sequence would have no benefit. It is also possible to complete an atomic update in Suspended state, or straddling an interval in Suspended state if Suspended state is entered via an interrupt or tsuspend, and exited via tremuse, rfebb, rfid, hrfid, or mtmsrd. However, an atomic update will not succeed if only one of the Load and Reserve / Store Conditional instruction pair is executed in Suspended state.

### Programming Note

Note that if a Store Conditional instruction within a transaction does not store, it may still be possible for the transaction to succeed. Software must not depend on the two operations having the same outcome. For example, software must not use success of an enclosing transaction as a replacement for checking the condition code from a transactional Store Conditional instruction.

### Virtualized Implementation Note

On a virtualized implementation, Case 3 includes reservation loss caused by the virtualization software. Thus, on a virtualized implementation, a reservation may be lost at any time without apparent cause. The virtualization software participates in any forward progress assurances, as described above.

### Programming Note

The architecture does not include a “fairness guarantee”. In competing for a reservation, two processors can indefinitely lock out a third.

### Programming Note

Accessing storage locations in Suspended state that have been accessed transactionally has the potential to create apparent storage paradoxes. Consider, for example, a case where variable X has initial value zero, is updated transactionally to one, is read in Suspended state, subsequently the transaction fails, and variable X is read again. In the absence of external conflicts, the observed sequence of values will be zero, one, zero: old, new, old.

Performing an atomic update on X in Suspended state may be even more confusing. Suppose the atomic sequence increments X, but that the only way to have X=1 is via the transactional store that occurs before entering Suspended state. The store conditional, if it succeeds, will store X=2 and in so doing, kill the transaction. But with the transaction having failed, X was never equal to one.

The flexibility of the Suspended state programming model can create unintuitive results. It must be used with care.

Successful transactions are serialized in some order, and no processor or mechanism is able to observe the accesses caused by any subset of these transactions as occurring in an order that conflicts with this order. Specifically, let processor i execute transactions 0, 1, ..., j, j+1, ..., where only successful transactions are numbered, and the numbering reflects program order. Let T_ij be transaction j on processor i. Then there is an ordering of the T_ij such that no processor or mechanism is able to observe the accesses caused by the transactions T_ij in an order that conflicts with this order.
ing. Note that Suspended state storage accesses are not included in the serialization property.

--- Programming Note ---

The ordering of the $T_{ij}$ for a given $i$ is consistent with program order for processor $i$.

Because of the difference between a transaction's instantaneous appearance and the finite time required to execute it in an implementation, it is exposed to changes in memory management state in a way that is not true for individual accesses. A change to the translation or protection state that would prevent any access from taking place at any time during its processing for the transaction compromises the integrity of the transaction. Any such change must either be prevented or must cause the transaction to fail. The architecture will automatically fail a transaction if the memory management state change is accomplished using $tlib$. An implementation may overdetect such conflicts between the $tlib$ and the transaction footprint. (Overdetection may result from the technique used to detect the conflict. A bloom filter may be used, as an example. Subsequent references to translation invalidation conflicts implicitly include any cases of spurious overdetection.) Changes made in some other manner must be managed by software, for example by explicitly terminating any affected transactions. Examples of instructions that require software management are $tlib$, $slbie$, $slbia$, and $tliba$.

The atomic nature of a transaction, together with the cumulative memory barrier created by the transaction and the memory barriers created by $tbegin$ and $tend$, described below, has the potential to eliminate the need for explicit memory barriers within the transaction, and before and after the transaction as well. However, since there may be a desire to preserve existing algorithms while exploiting transactions, the interaction of memory barriers and transactions is defined. In the presence of transactions, storage access ordering is the same as if no transactions are present, with the following exceptions. Memory barriers that are created while the transaction is running (other than the integrated cumulative memory barrier of the transaction described below), data dependencies, and SAO do not order transactional stores. Instead, transactional stores are grouped together into an "aggregate store," which is performed as an atomic unit with respect to other processors and mechanisms when the transaction succeeds, after all the transactional loads have been performed. With this store behavior, the appearance of transactional atomicity is created in a manner similarly to that for a Load and Reserve / Store Conditional pair. Success of the transaction is conditional on the storage locations specified by the loads not having been stored into by a more recent Suspended state store or by any store by another processor or mechanism since the load was performed. (There are additional conditions for the success of transactions.)

A $tbegin$, instruction that begins a successful transaction creates a memory barrier that immediately precedes the transaction and orders storage accesses pairwise, as follows. Let $A$ and $B$ be sets of storage accesses as defined below. For each pair $a_i b_j$ of storage accesses such that $a_i$ is in $A$ and $b_j$ is in $B$, the memory barrier ensures that $a_i$ will be performed with respect to any processor or mechanism, to the extent required by the associated Memory Coherence Required attributes, before $b_j$ is performed with respect to that processor or mechanism. Set $A$ contains all data accesses caused by instructions preceding the $tbegin$, that are neither Write Through Required nor Caching Inhibited. Set $B$ contains all data accesses caused by instructions following the $tbegin$, including Suspended state accesses, that are neither Write Through Required nor Caching Inhibited.

--- Programming Note ---

The reason the creation of the memory barrier by $tbegin$, is specified to be contingent on the transaction succeeding is that delaying the creation may improve performance, and does not seriously inconvenience software.

A successful transaction has an integrated memory barrier behavior. When a processor (P1) executes a $tend$, instruction and $tend$, processing determines that the transaction will succeed, a memory barrier is created, which orders storage accesses pairwise, as follows. Let $A$ and $B$ be sets of storage accesses as defined below. For each pair $a_i b_j$ of storage accesses such that $a_i$ is in $A$ and $b_j$ is in $B$, the memory barrier ensures that $a_i$ will be performed with respect to any processor or mechanism, to the extent required by the associated Memory Coherence Required attributes, before $b_j$ is performed with respect to that processor or mechanism. Set $A$ contains all non-transactional data accesses by other processors and mechanisms that have been performed with respect to P1 before the memory barrier is created and are neither Write Through Required nor Caching Inhibited. Set $B$ contains the aggregate store and all non-transactional data accesses by other processors and mechanisms that are performed after a Load instruction executed by that processor or mechanism has returned the value stored by a store that is in set $B$. Note that the cumulative memory barrier does not order Suspended state storage accesses interleaved with the transaction.

A $tend$, instruction that ends a successful transaction creates a memory barrier that immediately follows the transaction and orders storage accesses pairwise, as follows. Let $A$ and $B$ be sets of storage accesses as defined below. For each pair $a_i b_j$ of storage accesses such that $a_i$ is in $A$ and $b_j$ is in $B$, the memory barrier ensures that $a_i$ will be performed with respect to any processor or mechanism, to the extent required by the associated Memory Coherence Required attributes, before $b_j$ is performed with respect to that processor or mechanism.
mechanism. Set A contains all data accesses caused by instructions preceding the `tend`, including Suspended state accesses, that are neither Write Through Required nor Caching Inhibited. Set B contains all data accesses caused by instructions following the `tend` that are neither Write Through Required nor Caching Inhibited.

**Programming Note**

The barriers that are created by the execution of a successful transaction (those associated with `tbegin`, `tend`, and the integrated cumulative barrier) render most explicit barriers in and around transactions redundant. An exception is when there is a need to establish order among Suspended state accesses.

### 1.8.1 Rollback-Only Transactions

A Rollback-Only Transaction (ROT) is a sequence of instructions that is executed, or not, as a unit. The purpose of the ROT is to enable bulk speculation of instructions with minimum overhead. It leverages the rollback mechanism that is invoked as part of transaction failure handling, but has reduced overhead in that it does not have the full atomic nature of the transaction and its synchronization and serialization properties. The absence of a (normal) transaction's atomic quality means that a ROT must not be used to manipulate shared data.

More specifically, a ROT differs from a normal transaction as follows.

- ROTs are not serialized.
- There are no memory barriers created by `tbegin` and `tend`.
- A ROT has no integrated cumulative memory barrier.
- There is no monitoring of storage locations specified by loads for modification by other processors and mechanisms between the performing of the loads and the completion of the ROT.
- The stores that are included in the ROT need not appear to be performed as an aggregate store. (Implementations are likely to provide an aggregate store appearance, but the correctness of the program must not depend on the aggregate store appearance.)

In this section, including its subsections, it is assumed that all instructions for which execution is attempted are in storage that is not Caching Inhibited and (unless instruction address translation is disabled; see Book III-S) is not Guarded, and from which instruction fetching does not cause the system error handler to be invoked (e.g., from which instruction fetching is not prohibited by the “address translation mechanism” or the “storage protection mechanism”; see Book III).

**Programming Note**

The results of attempting to execute instructions from storage that does not satisfy this assumption are described in Section 1.6.2 and Section 1.6.4 of this Book and in Book III.

For each instance of executing an instruction from location X, the instruction may be fetched multiple times.

The instruction cache is not necessarily kept consistent with the data cache or with main storage. It is the responsibility of software to ensure that instruction storage is consistent with data storage when such consistency is required for program correctness.

After one or more bytes of a storage location have been modified and before an instruction located in that storage location is executed, software must execute the appropriate sequence of instructions to make instruction storage consistent with data storage. Otherwise the result of attempting to execute the instruction is boundedly undefined except as described in Section 1.9.1, “Concurrent Modification and Execution of Instructions” on page 752.

### 1.9 Instruction Storage

The instruction execution properties and requirements described in this section, including its subsections, apply only to instruction execution that is required by the sequential execution model.
Programming Note

Following are examples of how to make instruction storage consistent with data storage. Because the optimal instruction sequence to make instruction storage consistent with data storage may vary between systems, many operating systems will provide a system service to perform this function.

**Case 1:** The given program does not modify instructions executed by another program nor does another program modify the instructions executed by the given program.

Assume that location X previously contained the instruction A0; the program modified one of more bytes of that location such that, in data storage, the location contains the instruction A1; and location X is wholly contained in a single cache block. The following instruction sequence will make instruction storage consistent with data storage such that if the *isync* was in location X-4, the instruction A1 in location X would be executed immediately after the *isync*.

```plaintext
dcbst X  #copy the block to main storage sync    #order copy before invalidation icbi X  #invalidate copy in instr cache sync    #order invalidation before store # to flag stw r0,flag  #set flag indicating instruction # storage is now consistent
```

**Case 2:** One or more programs execute the instructions that are concurrently being modified by another program.

Assume program A has modified the instruction at location X and other programs are waiting for program A to signal that the new instruction is ready to execute. The following instruction sequence will make instruction storage consistent with data storage and then set a flag to indicate to the waiting programs that the new instruction can be executed.

```plaintext
li r0,1  #put a 1 value in r0 dcbst X  #copy the block in main storage sync    #order copy before invalidation icbi X  #invalidate copy in instr cache sync    #order invalidation before store # to flag stw r0,flag  #set flag indicating instruction # storage is now consistent
```

The following instruction sequence, executed by the waiting program, will prevent the waiting programs from executing the instruction at location X until location X in instruction storage is consistent with data storage, and then will cause any prefetched instructions to be discarded.

```plaintext
lwz r0,flag  #loop until flag = 1 (when 1 is cmpwi r0,1 # loaded, location X in inst’n bne $-8 # storage is consistent with # location X in data storage) isync    #discard any prefetched inst’ns
```

In the preceding instruction sequence any context synchronizing instruction (e.g., *rfid*) can be used instead of *isync*. (For Case 1 only *isync* can be used.)

For both cases, if two or more instructions in separate data cache blocks have been modified, the *dcbst* instruction in the examples must be replaced by a sequence of *dcbst* instructions such that each block containing the modified instructions is copied back to main storage. Similarly, for *icbi* the sequence must invalidate each instruction cache block containing a location of an instruction that was modified. The *sync* instruction that appears above between "*dcbst* X" and "*icbi* X" would be placed between the sequence of *dcbst* instructions and the sequence of *icbi* instructions.
1.9.1 Concurrent Modification and Execution of Instructions

The phrase “concurrent modification and execution of instructions” (CMODX) refers to the case in which a processor fetches and executes an instruction from instruction storage which is not consistent with data storage or which becomes inconsistent with data storage prior to the completion of its processing. This section describes the only case in which executing this instruction under these conditions produces defined results.

In the remainder of this section the following terminology is used.

- Location $X$ is an arbitrary word-aligned storage location.
- $X_0$ is the value of the contents of location $X$ for which software has made the location $X$ in instruction storage consistent with data storage.
- $X_1, X_2, ..., X_n$ are the sequence of the first $n$ values occupying location $X$ after $X_0$.
- $X_n$ is the first value of $X$ subsequent to $X_0$ for which software has again made instruction storage consistent with data storage.
- The “patch class” of instructions consists of the I-form Branch instruction ($b[l][a]$) and the preferred no-op instruction ($ori0,0,0$).

If the instruction from location $X$ is executed after the copy of location $X$ in instruction storage is made consistent for the value $X_0$ and before it is made consistent for the value $X_n$, the results of executing the instruction are defined if and only if the following conditions are satisfied.

1. The stores that place the values $X_1, ..., X_n$ into location $X$ are atomic stores that modify all four bytes of location $X$.
2. Each $X_i, 0 \leq i \leq n$, is a patch class instruction.
3. Location $X$ is in storage that is Memory Coherence Required.

If these conditions are satisfied, the result of each execution of an instruction from location $X$ will be the execution of some $X_i, 0 \leq i \leq n$. The value of the ordinate $i$ associated with each value executed may be different and the sequence of ordinates $i$ associated with a sequence of values executed is not constrained, (e.g., a valid sequence of executions of the instruction at location $X$ could be the sequence $X_i, X_{i+2}, X_{i+1}$). If these conditions are not satisfied, the results of each such execution of an instruction from location $X$ are boundedly undefined, and may include causing inconsistent information to be presented to the system error handler.

---

**Programming Note**

An example of how failure to satisfy the requirements given above can cause inconsistent information to be presented to the system error handler is as follows. If the value $X_0$ (an illegal instruction) is executed, causing the system illegal instruction handler to be invoked, and before the error handler can load $X_0$ into a register, $X_0$ is replaced with $X_1$, an Add Immediate instruction, it will appear that a legal instruction caused an illegal instruction exception.

---

**Programming Note**

It is possible to apply a patch or to instrument a given program without the need to suspend or halt the program. This can be accomplished by modifying the example shown in the Programming Note at the end of Section 1.9 where one program is creating instructions to be executed by one or more other programs.

In place of the Store to a flag to indicate to the other programs that the code is ready to be executed, the program that is applying the patch would replace a patch class instruction in the original program with a Branch instruction that would cause any program executing the Branch to branch to the newly created code. The first instruction in the newly created code must be an **isync**, which will cause any prefetched instructions to be discarded, ensuring that the execution is consistent with the newly created code. The instruction storage location containing the **isync** instruction in the patch area must be consistent with data storage with respect to the processor that will execute the patched code before the Store which stores the new Branch instruction is performed.

---

**Programming Note**

It is believed that all processors that comply with versions of the architecture that precede Version 2.01 support concurrent modification and execution of instructions as described in this section if the requirements given above are satisfied, and that most such processors yield boundedly undefined results if the requirements given above are not satisfied. However, in general such support has not been verified by processor testing. Also, one such processor is known to yield undefined results in certain cases if the requirements given above are not satisfied.
Chapter 2. Effect of Operand Placement on Performance

The placement (location and alignment) of operands in storage affects relative performance of storage accesses, and may affect it significantly. The best performance is guaranteed if storage operands are aligned to the natural boundary of the data accessed. Performance of storage accesses varies depending on the following:

1. Operand Size
2. Operand Alignment
3. Crossing no boundary
4. Crossing a cache block boundary
5. Crossing a virtual page boundary

Figure 1 on page 754 specifies which storage accesses that are permitted, but not necessarily required, to invoke the system alignment error handler, resulting in significantly degraded performance.

Specific platforms may set more restrictive requirements on which storage accesses an implementation is allowed to invoke the system alignment error handler.

The Move Assist instructions have no alignment requirements.

</table>

1. "N" means any N-byte alignment
   "odd N" means any N-byte alignment but not 2×N-byte alignment
   "< N" means any non-N-byte alignment
2. Including Move Assist instructions (*lswi*, *lswx*, *stswi*, and *stswx*).
3. For Category: Server, may be invoked when the storage access uses Little-Endian byte ordering or when the storage access spans a virtual page boundary.
   For Category: Embedded, may be invoked for any unaligned access.
4. Vector storage access instructions are always quadword-aligned.
5. May be invoked for any unaligned access.
2.1 Instruction Restart

In this section, “Load instruction” includes the Cache Management and other instructions that are stated in the instruction descriptions to be “treated as a Load”, and similarly for “Store instruction”.

The following instructions are never restarted after having accessed any portion of the storage operand (unless the instruction causes a “Data Address Watchpoint match”, for which the corresponding rules are given in Book III).

1. A Store instruction that causes an atomic access and, for the Embedded environment, accesses storage that is Guarded
2. A Load instruction that causes an atomic access to storage that is Guarded and, for the Server environment, is also Caching Inhibited.

Any other Load or Store instruction may be partially executed and then aborted after having accessed a portion of the storage operand, and then re-executed (i.e., restarted, by the processor or the operating system). If an instruction is partially executed, the contents of registers are preserved to the extent that the correct result will be produced when the instruction is re-executed. Additional restrictions on the partial execution of instructions are described in Section 6.6 of Book III-S and Section 7.7 of Book III-E.

--- Programming Note ---

In order to ensure that the contents of registers are preserved to the extent that a partially executed instruction can be re-executed correctly, the registers that are preserved must satisfy the following conditions. For any given instruction, zero or more of the conditions applies.

- For a fixed-point Load instruction that is not a multiple or string form, or for an eciw instruction, if RT=RA or RT=RB then the contents of register RT are not altered.
- For an update form Load or Store instruction, the contents of register RA are not altered.

--- Programming Note ---

There are many events that might cause a Load or Store instruction to be restarted. For example, a hardware error may cause execution of the instruction to be aborted after part of the access has been performed, and the recovery operation could then cause the aborted instruction to be re-executed.

When an instruction is aborted after being partially executed, the contents of the instruction pointer indicate that the instruction has not been executed, however, the contents of some registers may have been altered and some bytes within the storage operand may have been accessed. The following are examples of an instruction being partially executed and altering the program state even though it appears that the instruction has not been executed.

1. Load Multiple, Load String: Some registers in the range of registers to be loaded may have been altered.
2. Any Store instruction, dcbz: Some bytes of the storage operand may have been altered.
Chapter 3. Management of Shared Resources

The facilities described in this section provide the means to control the use of resources that are shared with other processors.

3.1 Program Priority Registers

The Program Priority Register (PPR) is a 64-bit register that controls the program’s priority. The PPR provides access to the full 64-bit PPR, and the Program Priority Register 32-bit (PPR32) provides access to the upper 32 bits of the PPR. The Embedded environment only provides access to PPR32. The layouts of the PPR and PPR32 are shown in Figure 2.

<table>
<thead>
<tr>
<th>Bit(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>11:13</td>
<td>Program Priority (PRI) (PPR32:43:45)</td>
</tr>
<tr>
<td>001</td>
<td>very low</td>
</tr>
<tr>
<td>010</td>
<td>low</td>
</tr>
<tr>
<td>011</td>
<td>medium low</td>
</tr>
<tr>
<td>100</td>
<td>medium</td>
</tr>
<tr>
<td>101</td>
<td>medium high</td>
</tr>
</tbody>
</table>

Programs can always set the PRI field to very low, low, medium low, and medium priorities; programs may be allowed to set the PRI field to medium high priority during certain time intervals. (See Section 4.3.6.) If the program priority is medium high when the time interval expires or if an attempt is made to set the priority to medium high when it is not allowed, the PRI field is set to medium.

If other values are written to this field, the PRI field is not changed. (See Section 4.3.5 of Book III-S for additional information.)

All other fields are reserved.

Figure 2. Program Priority Register

Programming Note

The ability to access the low-order half of the PPR (and thus the use of mfppr and mtppr) might be phased out in a future version of the architecture.

Programming Note

By setting the PRI field, a programmer may be able to improve system throughput by causing system resources to be used more efficiently.

E.g., if a program is waiting on a lock (see Section B.2), it could set low priority, with the result that more processor resources would be diverted to the program that holds the lock. This diversion of resources may enable the lock-holding program to complete the operation under the lock more quickly, and then relinquish the lock to the waiting program.

Programming Note

or Rx,Rx,Rx can be used to modify the PRI field; see Section 3.2.

Programming Note

When the system error handler is invoked, the PRI field may be set to an undefined value.

3.2 “or” Instruction

Setting the PPR

The or Rx,Rx,Rx (see Book I) instruction can be used to set PPRPRI as shown in Figure . or. Rx,Rx,Rx does not set PPRPRI.

<table>
<thead>
<tr>
<th>Rx</th>
<th>PPRPRI</th>
<th>Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>001</td>
<td>very low</td>
</tr>
<tr>
<td>1</td>
<td>010</td>
<td>low</td>
</tr>
<tr>
<td>6</td>
<td>011</td>
<td>medium low</td>
</tr>
<tr>
<td>2</td>
<td>100</td>
<td>medium</td>
</tr>
<tr>
<td>5</td>
<td>101</td>
<td>medium high</td>
</tr>
</tbody>
</table>
Priority levels for or Rx,Rx,Rx

Programs can always set the PRI field to very low, low, medium low, and medium priorities; programs may be allowed to set the PRI field to medium high priority during certain time intervals. (See Section 4.3.6 of Book III-S.) If the program priority is medium high when the time interval expires or if an attempt is made to set the priority to medium high when it is not allowed, the PRI field is set to medium.

The following forms of or Rx,Rx,Rx provide hints about usage of shared processor resources.

“or” Shared Resource Hints

or 27,27,27

This form of or provides a hint that performance will probably be improved if shared resources dedicated to the executing processor are released for use by other processors.

or 29,29,29

This form of or provides a hint that performance will probably be improved if shared resources dedicated to the executing processor are released until all outstanding storage accesses to caching-inhibited storage have been completed.

or 30,30,30

This form of or provides a hint that performance will probably be improved if shared resources dedicated to the executing processor are released until all outstanding storage accesses to cacheable storage for which the data is not in the cache have been completed.

Extended Mnemonics:

Additional extended mnemonics for the or hints:

<table>
<thead>
<tr>
<th>Extended</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>yield</td>
<td>or 27,27,27</td>
</tr>
<tr>
<td>mdoio</td>
<td>or 29,29,29</td>
</tr>
<tr>
<td>mdoom</td>
<td>or 30,30,30</td>
</tr>
</tbody>
</table>

**Programming Note**

**Warning:** Other forms of or Rx,Rx,Rx that are not described in this section and in Section 4.3.3, “or” Instruction”, in Book II may also cause program priority to change. Use of these forms should be avoided except when software explicitly intends to alter program priority. If a no-op is needed, the preferred no-op (ori 0,0,0) should be used.
Chapter 4. Storage Control Instructions

4.1 Parameters Useful to Application Programs

It is suggested that the operating system provide a service that allows an application program to obtain the following information.

1. The virtual page sizes
2. Coherence block size
3. Reservation granule size
4. An indication of the cache model implemented (e.g., Harvard-style cache, combined cache)
5. Instruction cache size
6. Data cache size
7. Instruction cache block size
8. Data cache block size
9. Instruction cache associativity
10. Data cache associativity
11. Number of stream IDs supported for the stream variant of *dcbt*
12. Factors for converting the Time Base to seconds
13. Maximum transaction level

If the caches are combined, the same value should be given for an instruction cache attribute and the corresponding data cache attribute.

4.2 Data Stream Control Register (DSCR) [Category: Stream]

The layout of the Data Stream Control Register (DSCR) is shown in Figure 3 below.

<table>
<thead>
<tr>
<th>Bit(s)</th>
<th>Description</th>
<th>Value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>39</td>
<td>Software Transient Enable (SWTE)</td>
<td>0   Must be 1 to apply the transient attribute to software-defined streams.</td>
</tr>
<tr>

<td>1   Applies the unit count to software-defined streams.</td>
</tr>
<tr>
<td>44</td>
<td>Hardware Unit count Enable (HWUE)</td>
<td>0   HWUE is disabled.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1   Applies the unit count to hardware-detected streams.</td>
</tr>
<tr>
<td>45:54</td>
<td>Unit Count (UNITCNT)</td>
<td>Number of units in data stream.</td>
</tr>
<tr>
<td>55:57</td>
<td>Depth Attainment Urgency (URG)</td>
<td>This field indicates how quickly the prefetch depth should be reached for hardware-detected streams. Values and their meanings are as follows.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0   default</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1   not urgent</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2   least urgent</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3   less urgent</td>
</tr>
<tr>
<td></td>
<td></td>
<td>4   medium</td>
</tr>
<tr>
<td></td>
<td></td>
<td>5   urgent</td>
</tr>
<tr>
<td></td>
<td></td>
<td>6   more urgent</td>
</tr>
<tr>
<td></td>
<td></td>
<td>7   most urgent</td>
</tr>
<tr>
<td>58</td>
<td>Load Stream Disable (LSD)</td>
<td>0   No effect.</td>
</tr>
</tbody>
</table>

Figure 3. Data Stream Control Register
1 Disables hardware detection and initiation of load streams.

59 **Stride-N Stream Enable (SNSE)**

0 No effect.
1 Enables the hardware detection and initiation of load and store streams that have a stride greater than a single cache block. Such load streams are detected only when LSD is also zero. Such store streams are detected only when SSE is also one.

61:63 **Default Prefetch Depth (DPFD)**

This field supplies a prefetch depth for hardware-detected streams and for software-defined streams for which a depth of zero is specified or for which `dcbt/dcbtst` with `TH=1010` is not used in their description. Values and their meanings are as follows.

- 0 default (LPCRDPFD)
- 1 none
- 2 shallowest
- 3 shallow
- 4 medium
- 5 deep
- 6 deeper
- 7 deepest

The contents of the DSCR affect how a processor handles hardware-detected and software-defined data streams. The DSCR provides the only means by which software can control or supply information for hardware-detected data streams. The DPFD, UNITCNT, and transient fields may also be used instead of the `TH=01010` variant of `dcbt` for software-defined data streams, especially when multiple streams have these attributes in common. See Section 4.3.2, “Data Cache Instructions” on page 763, for information on streams and how software may specify them.

**Programming Note**

The purpose of Depth Attainment Urgency is to regulate the rate of prefetch generation from the cycle at which the hardware first detects an incipient stream until the cycle when the prefetch Depth is reached. A more urgent setting will benefit applications that are dominated by short to medium length streams, because otherwise prefetching does not occur rapidly enough to benefit them. In contrast, applications that frequently cause unproductive prefetches due to stream mispredicts will benefit from a less urgent setting.

Unlike the Depth, the Depth Attainment Urgency applies only to hardware-detected streams. Furthermore, the DSCR provides the only point of control for this parameter. Software-defined streams are assumed not to have the correctness risk associated with hardware streams, and therefore are set to reach their depth relatively quickly.

**Programming Note**
