

# EDAF50 – C++ Programming

## *11. Low-level details. Loose ends.*

Sven Gestegård Robertz  
*Computer Science, LTH*

2022

# Outline

## 1 Bit operations

- bit-fields
- <bitset>

## 2 Multi-dimensional arrays

- Parentheses

## 3 C-style strings

- The C standard library string functions
- C-strings – details and warnings

## 4 Types

- Integer types

## 5 Syntax

- Most vexing parse
- The comma operator

## 6 Object slicing

# Bitwise operators

Bitwise and: `a & b`

shift left: `a << 5`

Bitwise or: `a | b`

shift right: `a >> 5`

Bitwise xor: `a ^ b`

*>> on signed types is  
implementation defined*

Bitwise complement: `~a`

Common operations:

set 5th bit

```
a = a | (1 << 4);  
a |= (1 << 4);
```

clear 5th bit

```
a = a & ~(1 << 4);  
a &= ~(1 << 4);
```

toggle 5th bit

```
a = a ^ (1 << 4);  
a ^= (1 << 4);
```

# Bitwise operators

Example:

## Low-level operations: Bitwise operators

All variables are unsigned 16 bit integers

```
a = 77;           // a = 0000 0000 0100 1101
b = 22;           // b = 0000 0000 0001 0110
c = ~a;           // c = 1111 1111 1011 0010
d = a & b;         // d = 0000 0000 0000 0100
e = a | b;         // e = 0000 0000 0101 1111
f = a ^ b;         // f = 0000 0000 0101 1011
g = a << 3;        // g = 0000 0010 0110 1000
h = c >> 5;        // h = 0000 0111 1111 1101
i = a & 0x000f;      // i = 0000 0000 0000 1101
j = a | 0xf000;      // j = 1111 0000 0100 1101
k = a ^ (1 << 4);    // k = 0000 0000 0101 1101
```

# Bit-fields

Can be used to save memory

Specify explicit size in bits with var : bit\_width

```
struct Car { // record in a car database
    static constexpr int reg_sz = 6;
    char reg_nr[reg_sz];  NB! not null-terminated.
    unsigned int model_year : 12;
    bool tax_paid : 1;
    bool inspected : 1;
};
```

*sizeof(Car) = 8 on my computer*

# Bit-fields Example

## Access of members

```
Car c;  
  
strncpy(c.reg_nr, "ABC123", Car::reg_sz);  
c.model_year = 2011;  
c.tax_paid = true;  
c.inspected = true;  
  
cout << "Year: " << c.model_year << '\n';  
if (c.tax_paid && c.inspected)  
    cout << std::string(c.reg_nr, c.reg_nr+Car::reg_sz) << " is OK\n";
```

## Bit-fields Warnings

Bit-fields can be useful in special cases, but they are *not portable*

- ▶ the layout of the object is *implementation defined*
- ▶ the compiler can add *padding*
- ▶ bit-field members *have no address*
  - ▶ cannot use the address-of operator &
- ▶ always specify **signed** or **unsigned**
- ▶ access can be slower than a “normal” struct
- ▶ integer variables and bitwise operations is an alternative

## `std::bitset (<bitset>)`

- ▶ efficient class for storing a set of bits
  - ▶ compact
  - ▶ fast
- ▶ has convenient functions
  - ▶ test, **operator[]**
  - ▶ set, reset, flip
  - ▶ any, all, none, count
  - ▶ conversion to/from string
  - ▶ I/O operators
- ▶ cf. `std::vector<bool>`
  - ▶ `std::bitset` has fixed size
  - ▶ a `std::vector` can grow
  - ▶ but does not quite behave like a normal `std::vector<T>`

## bitset

Example: store 50 flags in 8 bytes

```
void test_bitop(){
    bool status;
    cout << std::boolalpha;

    unsigned long quizA = 0;

    quizA |= 1UL << 27 ;
    status = quizA & (1UL << 27);
    cout << "student 27: " ;
    cout << status << endl;

    quizA &= ~(1UL << 27);
    status = quizA & (1UL << 27);
    cout << "student 27: ";
    cout << status << endl;
}

student 27: true
student 27: false
```

```
void test_bitset(){
    bool status;
    cout << std::boolalpha;

    std::bitset<50> quizB;

    quizB.set(27);
    status = quizB[27];
    cout << "student 27: " ;
    cout << status << endl;

    quizB.reset(27);
    status = quizB[27];
    cout << "student 27: ";
    cout << status << endl;
}

student 27: true
student 27: false
```

# Multidimensional arrays

## multi-dimensional arrays

- ▶ Does not (really) exist in C++
  - ▶ are arrays of arrays
  - ▶ Look like in Java
- ▶ Java: array of *references to arrays*
- ▶ C++: two alternatives
  - ▶ Array of arrays
  - ▶ Array of *pointers* (*to the first element of an array*)

# Multi-dimensional arrays

## Representation of arrays in memory

An array `T array[3]` is represented in memory by a sequence of three elements of type `T`: | T | T | T |

An array `int a1[4]` is represented as

| int | int | int | int |

Thus, `int a2[3][4]` is represented as three `int[4]` objects:

| int |

# Multi-dimensional arrays

Initializing a matrix with an initializer list:

3 rows, 4 columns

```
int a[3][4] = {  
    {0, 1, 2, 3} , /* initializer list for row 0 */  
    {4, 5, 6, 7} , /* initializer list for row 1 */  
    {8, 9, 10, 11} /* initializer list for row 2 */  
};
```

Instead of nested lists one can write the initialization as a single list:

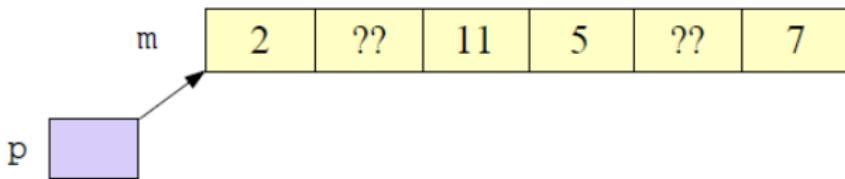

```
int a[3][4] = {0,1,2,3,4,5,6,7,8,9,10,11};
```

- ▶ Multi-dimensional arrays are stored like an array in memory.
- ▶ The dimension *closest to the name* is the size of the array
- ▶ The remaining dimensions belong to the element type

# Multi-dimensional arrays

## Examples

```
int m[2][3]; // A 2x3-matrix  
  
m[1][0] = 5;  
  
int* e = m;           // Error! cannot convert 'int [2][3]' to 'int*'  
int* p = &m[0][0];  
*p = 2;  
  
p[2] = 11;  
int* q=m[1];         // OK: int[3] decays to int*  
q[2] = 7;
```

# Multi-dimensional arrays

## Parameters of type multi-dimensional arrays

```
// One way of declaring the parameter
void printmatr(int (*a)[4], int n);

// Another option
void printmatr(int a[][4], int n) {
{
    for (int i=0;i<n;++i) {
        for (const auto& x : a[i]) { The elements of a are int[4]
            cout << x << " ";
        }
        cout << endl;
    }
}
```

# Multi-dimensional arrays

## Initialization and function call

```
int a[3][4] {1,2,3,4,5,6,7,8,9,10,11,12};  
int b[3][4] {{1,2,3,4},{5,6,7,8},{9,10,11,12}};  
  
printmatr(a,3);  
cout << "-----" << endl;  
printmatr(b,3);
```

1	2	3	4
5	6	7	8
9	10	11	12
-----			
1	2	3	4
5	6	7	8
9	10	11	12

# Declarations and parentheses

- ▶ Parentheses matter in declarations of pointers to arrays and functions
  - ▶ `int *a[10]` declares `a` as an array of `int*`
  - ▶ `int (*a)[10]` declares `a` as a pointer to `int[10]`
  - ▶ `int (&a)[10]` declares `a` as a reference to `int[10]`
  - ▶ `int (*f)(int)` declares `f` as a pointer to function `int → int`
- ▶ BUT may be used anywhere

```
struct Foo;

Foo test;
Foo(f);           // Foo f;

int x;
int(y);          // int y;
int(z){17};       // int z{17};
int(q){}:         // int q{};
```

# C-strings – library functions

## functions in <cstring>

```
strcpy(dest,src)      // Copies src to dest
strncpy(dest,src,n)   // Copies at most n chars
NB! dest is not null-terminated when truncating

strcat(s,t)           // Appends a copy of t to the end of s
strncat(s,t,n)        // Appends at most n chars

strlen(s)              // Gives the length of s
strlen(s,n)            // Gives the length of s, max n chars

strcmp(s,t)            // Compare s and t
strncmp(s,t,n)         // ... at most n chars
// s<t, s==t, s>t returns <0, =0, >0 respectively
```

(even more) unsafe, avoid when possible!

# String input

## Example mistake

The read string does not fit in x

The statements

```
char z[] {"zzzz"};
char y[] {"yyyy"};
char x[5];

stringstream sin{"aaaaaaaaaaaaaaa bbbbbbb"};
sin >> x;

cout << x << " : " << y << " : " << z << endl;
```

Give the output (on my computer):

aaaaaaaaaaaaaaa : **aa** : zzzz

- ▶ C-strings don't do bounds checking
- ▶ the input to x has overwritten (part of) y
- ▶ `getline()` is safer

# Copying strings

## Failing example

### The statements

```
char s[20];  
  
strncpy(s, "abc", 4);  
cout << s << endl;  
  
strncpy(s, "kalle anka", 20);  
cout << s << endl;  
  
strncpy(s, "def", 3);  
cout << s << endl;
```

### produce the output

```
abc  
kalle anka  
defle anka
```

### The statements

```
int data[] {558646598, 65, 66};  
char x[16];  
char t[30] {"test"};  
  
strncpy(x, "abcdefghijklmноп", 16);  
strcpy(t,x);  
cout << t << endl;
```

### produce the output

```
abcdefghijklмнопFEL!A
```

### Note

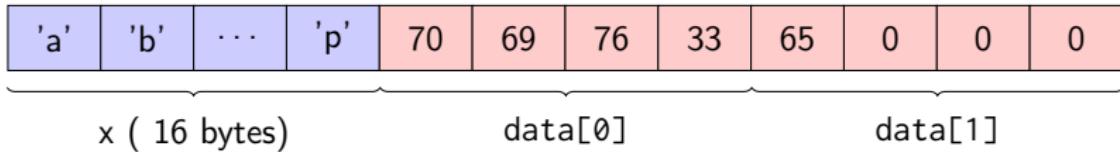

- `strncpy` does not terminate the string with a `\0` when truncating.
- `strcpy` copies until it finds a `\0` in src.

# Copying strings

## Failing example: explanation

```
int data[] { 558646598, 65, 66};  
char x[16];
```

- ▶ the bytes of `data` is interpreted as `char`.
- ▶ representation in memory

Hexadecimal representation:

$$558646598_{10} = 214c4546_{16}$$

$$65_{10} = 41_{16}$$

Byte order: *little-endian*

hex	ASCII)	dec
46	F	70
45	E	69
4c	L	76
21	!	33
41	A	65
0	\0	0
0	\0	0
0	\0	0
...	...	...

# Integer types

## ► Signed integers

Type	Size	Range (at least)
<code>signed char</code>	8 bits	$[-127, 127]^*$
<code>short</code>	at least 16 bits	$[-2^{15} + 1, 2^{15} - 1]$
<code>int</code>	at least 16 bits, usually 32	$[-2^{15} + 1, 2^{15} - 1]$
<code>long</code>	at least 32 bits	$[-2^{31} + 1, 2^{31} - 1]$
<code>long long</code>	at least 64 bits	$[-2^{63} + 1, 2^{63} - 1]$

\*typically  $[-128, 127]$ , etc.

## ► Unsigned integers

- same size as corresponding `signed` type
- `unsigned char`:  $[0, 255]$  , `unsigned short`:  $[0, 2^{16} - 1]$ . etc.

## ► special case

- `char` (can be *represented* as `signed char` or `unsigned char`)
- Use `char` only for characters
- Use `signed char` or `unsigned char` for integer values

## ► Sizes according to the standard:

`char`  $\leq$  `short`  $\leq$  `int`  $\leq$  `long`  $\leq$  `long long`

# Integer types

## Overflow

- ▶ overflow of an **unsigned** n-bit integer is defined as *the value modulo  $2^n$*
- ▶ overflow of a **signed** integer is *undefined*

# Integer types

## Example with sizeof

```
#include <iostream>
using namespace std;
int main () {
    cout << "sizeof(char)= \t" << sizeof(char)<<endl;
    cout << "sizeof(short)= \t" << sizeof(short) <<endl;
    cout << "sizeof(int) = \t" << sizeof(int) <<endl;
    cout << "sizeof(long)= \t" << sizeof(long)<<endl;
}
sizeof(char)=    1
sizeof(short)=   2
sizeof(int) =    4
sizeof(long)=   8
```

# Integer types

Sizes are specified in <climits>

CHAR_BIT	Number of bits in a <b>char</b> object (byte) (>=8)
SCHAR_MIN	Minimum value for an object of type <b>signed char</b>
SCHAR_MAX	Maximum value for an object of type <b>signed char</b>
UCHAR_MAX	Maximum value for an object of type <b>unsigned char</b>
CHAR_MIN	Minimum value for an object of type <b>char</b> (either SCHAR_MIN or 0)
CHAR_MAX	Maximum value for an object of type <b>char</b> (either SCHAR_MAX or UCHAR_MAX)
SHRT_MIN	Minimum value for an object of type <b>short int</b>
SHRT_MAX	Maximum value for an object of type <b>short int</b>
USHRT_MAX	Maximum value for an object of type <b>unsigned short int</b>
INT_MIN	Minimum value for an object of type <b>int</b>
INT_MAX	Maximum value for an object of type <b>int</b>
UINT_MAX	Maximum value for an object of type <b>unsigned int</b>
LONG_MIN	Minimum value for an object of type <b>long int</b>
LONG_MAX	Maximum value for an object of type <b>long int</b>
ULONG_MAX	Maximum value for an object of type <b>unsigned long int</b>
LLONG_MIN	Minimum value for an object of type <b>long long int</b>
LLONG_MAX	Maximum value for an object of type <b>long long int</b>
ULLONG_MAX	Maximum value for an object of type <b>unsigned long long</b>

# Integer types

Sizes are specified in <climits>

```
#include <iostream>
#include <climits>
int main()
{
    std::cout << CHAR_MIN << ", " << CHAR_MAX << ", ";
    std::cout << UCHAR_MAX << std::endl;
    std::cout << SHRT_MIN << ", " << SHRT_MAX << ", ";
    std::cout << USHRT_MAX << std::endl;
    std::cout << INT_MIN << ", " << INT_MAX << ", ";
    std::cout << UINT_MAX << std::endl;
    std::cout << LONG_MIN << ", " << LONG_MAX << ", ";
    std::cout << ULONG_MAX << std::endl;
    std::cout << LLONG_MIN << ", " << LLONG_MAX << ", ";
    std::cout << ULLONG_MAX << std::endl;
}

128, 127, 255
-32768, 32767, 65535
-2147483648, 2147483647, 4294967295
-9223372036854775808, 9223372036854775807, 18446744073709551615
-9223372036854775808, 9223372036854775807, 18446744073709551615
```

## Integer types

Sizes are implementation defined

Typedefs for specific sizes are in `<cstdint>` (`<stdint.h>`)

- ▶ integer types with exact width (if such a type exists):

```
int8_t int16_t int32_t int64_t
```

- ▶ fastest signed integer type with at least the width

```
int_fast8_t int_fast16_t int_fast32_t int_fast64_t
```

- ▶ smallest signed integer type with at least the width

```
int_least8_t int_least16_t int_least32_t int_least64_t
```

- ▶ signed integer type capable of holding a pointer:

```
intptr_t
```

- ▶ unsigned integer type capable of holding a pointer:

```
uintptr_t
```

The corresponding unsigned typedefs are named `uint_...._t`

# Most vexing parse

## Example 1

```
struct Foo {  
    int x;  
};  
  
int main()  
{  
#ifdef ERROR1  
    Foo f(); // function declaration  
#else  
    Foo f{}; // Variable declaration C++11  
    // Foo f; //C++98 (but not initialized)  
#endif  
    cout << f.x << endl; // Error  
  
    Foo g = Foo(); // OK      // C++11: auto g = Foo();  
    cout << g.x << endl;  
  
error: request for member 'x' in 'f', which is of  
non-class type 'Foo()'
```

# Most vexing parse

## Example 2

```
struct Foo {
    int x;
};

struct Bar {
    int x;
    Bar(Foo f) :x{f.x} {}
};

int main()
{
#define ERROR2
    Bar b(Foo()); // function declaration
#else
    Bar b{Foo()}; // Variable declaration (C++11)
    // Bar b((Foo())); // C++98 : extra parentheses --> expression
#endif
    cout << b.x << endl; // Error!

error: request for member 'x' in 'b', which is of
non-class type 'Bar(Foo (*)())'
```

# Most vexing parse

Example: actual function

```
struct Foo {  
    Foo(int i=0) :x{i} {}  
    int x;  
};  
  
struct Bar {  
    int x;  
    Bar(Foo f) :x{f.x} {}  
};  
  
Bar b(Foo()); // forward declaration
```

```
Foo make_foo()  
{  
    return Foo(17);  
}  
  
Bar b(Foo(*f)())  
{  
    return Bar(f());  
}
```

```
void test()  
{  
    Bar tmp = b(make_foo());  
    cout << tmp.x << endl;  
}
```

17

# The comma operator (Introduction and warning)

The comma operator expression expression1, expression2

- ▶ First evaluates expression1, then expression2
- ▶ the expression has the value of expression2
- ▶ NB! The comma separating function parameters or arguments is *not* the comma operator

```
string s;
while(cin >> s, s.length() > 5) {           // better: use &&
    //do something
}

template <class _OutputIterator, class _Size, class _Generator>
_OutputIterator
generate_n(_OutputIterator __first, _Size __n, _Generator __gen)
{
    for (; __n > 0; ++__first, --__n)
        *__first = __gen();
    return __first;
}
```

Avoid using the comma operator!

# Example

## A class hierarchy

```
struct Foo{
    virtual void print() const {cout << "Foo" << endl;}
};

struct Bar : Foo{
    void print() const override {cout << "Bar" << endl;}
};

struct Qux : Bar{
    void print() const override {cout << "Qux" << endl;}
};
```

# Polymorph class example, *object slicing*

What is printed?

```
void print1(const Foo* f)
{
    f->print();
}
void print2(const Foo& f)
{
    f.print();
}
void print3(Foo f)
{
    f.print();
}
```

```
void test()
{
    Foo* a = new Bar;
    Bar& b = *new Qux;
    Bar c = *new Qux;

    print1(a); Bar
    print1(&b); Qux
    print1(&c); Bar

    print2(*a); Bar
    print2(b); Qux
    print2(c); Bar

    print3(*a); Foo
    print3(b); Foo
    print3(c); Foo
}
```
