EDAF50 – C++ Programming

1. Introduction

Sven Gestegård Robertz

Computer Science, LTH

2024

Outline

1 About the course

2 Presentation of C++
- History
- Introduction
- Functions

EDAF50: C++ programming, 7.5 hp

The course gives detailed knowledge about C++. Special emphasis is placed on the language constructs that make C++ a more advanced, and also more complex, language than Java.

Knowledge and understanding

- ▶ know about and be able to describe the differences between C++ and Java
- ▶ have detailed knowledge about C++ and the standard library STL

Competences and skills

- ▶ be able to choose the correct language construct to solve a given problem
- ▶ be able to systematically debug C++ code
- ▶ be able to use tools to develop C++ programs in a Unix environment

EDAF50: C++ programming , 7.5 hp
Important differences to Java

New or extended concepts in C++
(compared to Java / introductory courses):

- ▶ Pointers and memory management
- ▶ Functions: call-by-value and call-by-reference
- ▶ Polymorphism: both static and dynamic
  (compare *templates* to *generics*)
- ▶ Operator overloading

EDAF50: C++ programming , 7.5 hp
Examination details

The compulsory course items are

▶ laborations
▶ project
▶ written examination

The final grade is based on the result of the written examination.

1967: Simula (Dahl & Nygaard)
1972: C (Dennis Ritchie)
1978: K&R C (Kernighan & Ritchie)
1980: C with Classes (Bjarne Stroustrup)
1985: C++ (Bjarne Stroustrup)

▶ ISO standard 1998

Other relatives:

1995: Java (James Gosling et al.)
2000: C# (Anders Hejlsberg)

▶ virtual machine
▶ automatic memory management
▶ *safe* languages

C++ is not a pure extension of C

- ▶ both ISO C and ISO C++ are descendants of K&R C, and are "siblings"
- ▶ some details are incompatible between ISO C och C++
- ▶ Areas are not to scale

In general: Don't write C++ as if it were C

What is C++?

The ISO standard for C++ defines two things

- ▶ *Core language features*, e.g.,
    - ▶ data types (e.g., `char`, `int`)
    - ▶ control flow mechanisms (e.g., `if` and `while` statements).
    - ▶ rules for declarations
    - ▶ templates
    - ▶ exceptions

- ▶ *Standard-library components*, e.g.,
    - ▶ Data structures (e.g., `string`, `vector`, and `map`)
    - ▶ Operations for in- and output (e.g., `<<` and `getline()`)
    - ▶ Algorithms (e.g., `find()` and `sort()`)

The standard library is written in C++

- ▶ Example of what is possible

A minimal program in C++

empty.cc

```cpp
int main( ) { }
```

- ▶ has no parameters
- ▶ does nothing
- ▶ the return value of `main()` is interpreted by the system as an error code
  - ▶ non-zero means error
  - ▶ no explicit return value is interpreted as zero (NB! only in `main()`)
  - ▶ rarely used in Windows
  - ▶ often used on Linux/Mac

The first C++ program
Hello, World!

hello.cc

```cpp
#include <iostream>
int main( )
{
    std::cout << "Hello, World!" << std::endl;
    return 0;
}
```
hello.cc

```cpp
#include <iostream>
using std::cout;
using std::endl;

int main( )
{
    cout << "Hello, World!" << endl;
    return 0;
}
```

What is a program?

C++ is a compiled language
- ▶ Source code
- ▶ Object file(s)
- ▶ Executable file

A C++ program

Example: compute and print x^2.

```cpp
#include <iostream>

double square(double x)
{
  return x*x;
}

void print_square(double d)
{
    std::cout << "the square of " << d <<
                " is " << square(d) << std::endl;
}

int main( )
{
    print_square(1.234);
    return 0;
}
```

Functions
Declaration and definition

The main way of getting sonething done in C++:

- ▶ call a *function*
    - ▶ Declare before use
      A function must have been *declared* before it can be called
    - ▶ A function declaration specifices
        - ▶ name
        - ▶ return type
        - ▶ types of the parameters
    - ▶ Example: function declarations
      ```
      int random();
      void exit(int);
      double square(double);
      int pow(int x, int exponent);
      ```
        - ▶ The compiler ignores parameter names
        - ▶ Give names if it increases readability

- ▶ A function *definition* contains the implementation
    - ▶ Must only occur once

Difference from Java
Function and variable declarations

- ► In Java functions and variables
  can only be declared inside a class.

- ► In C++, functions and variables
  can exist independently of classes.

    - ► free functions do not belong to a class
    - ► member functions in a class

    - ► global variables
    - ► member variables

Function declaration
Example

▶ Declaration and definition

Example: Mean value – variant 1

```cpp
double mean(double x1, double x2) // Declaration and definition
{
    return (x1+x2)/2;
}

int main()
{
    double a=2.3, b=3.9;
    cout << mean(a, b) << endl;
}
```

Function definition
With forward declaration

- ▶ Fuction declaration before use in `main()`
- ▶ Fuction definition elsewhere

Example: mean – variant 2

```
double mean(double, double);            // declaration (prototype)
                                                            mean.h
```
```
int main()
{
   double a=2.3, b=3.9;
   std::cout << mean(a, b) << endl;      // use
}                                                          main.cc
```
```
                                                          mean.cc
double mean(double x1, double x2)    //definition
{
   return (x1+x2)/2;
}
```

Function definition
With forward declaration

- ▶ Fuction declaration before use in `main()`
- ▶ Fuction definition elsewhere

Example: mean – variant 2

```
double mean(double, double);          // declaration (prototype)
                                                            mean.h

#include <iostream>
#include "mean.h"

int main()
{
    double a=2.3, b=3.9;
    std::cout << mean(a, b) << endl;        // use
}                                                           main.cc
                                                            mean.cc
double mean(double x1, double x2)     //definition
{
    return (x1+x2)/2;
}
```

The semantics of function argument passing is the same as
copy initialization: *(Same as for primitive types in Java)*

- ▶ In a function call, the *values of the arguments* are
  - ▶ type checked, and
  - ▶ with implicit type conversion (if needed)
  - ▶ copied to the function parameters

- ▶ Example: with a function **double** square(**double** d)

  ```
  double s2 = square(2);      // 2 is converted to double
                              // double d = 2;

  double s3 = square("three"); // error
                              // double d = "three";
  ```

Functions
Function overloading

- Overloading ("överlagring")

```cpp
void print(int);
void print(double);
void print(std::string);

void user()
{
    print(42);      // calls print(int);
    print(1.23);    // calls print(double);
    print(4.5f);    // calls print(double);
    print("Hello")  // calls print(std::string);
}
```

- Cannot differ only in return type
- Must not be ambiguous

- Default arguments (sometimes) similar to overloading
    - **void** print(**int** x, std::ostream& out = std::cout);
    - The rules are complex. *Only use for trivial cases*
    - Risk of ambiguity if combined with overloading

▶ With overloaded functions, the compiler selects "the best"
  function (after implicit type conversion)

▶ If two alternatives are "equally good matches " it is an error

```cpp
void print2(int, double);
void print2(double, int);

void user()
{
    print2(0, 0);    // Error! ambiguous
}
```

▶ and also (with print() from last slide)

```cpp
long l = 17;
print(l);          // Error! print(int) or print(double)?
```

Functions
Rule of thumb

Factor your code into small functions to

- ▶ give names to activities and document their dependencies
- ▶ avoid writing specific code in the middle of other code
- ▶ facilitate testing

- ▶ A function should perform a single task
- ▶ Keep functions as short as possible
- ▶ Rule of thumb
  - ▶ Max 24 lines
  - ▶ Max 80 columns
  - ▶ Max 3 block levels
  - ▶ Max 5–10 local variables
  - ▶ Inversely proportional to complexity

In a 'normal' function call, the values of the arguments are copied to the formal parameters (which are local variables)

Example: swap two integer values

```cpp
void swap(int a, int b)
{
    auto tmp=a;    // int tmp = a;
    a = b;
    b = tmp;
}
```

...and use:

```cpp
int x = 2;
int y = 10;

swap(x, y);

cout << x ", " << y << endl;     2,10    x and y are not changed
```

Use *call by reference* instead of *call by value*:

Example: swap two integer values

```cpp
void swap(int& a, int& b)
{
    auto tmp=a;
    a = b;
    b = tmp;
}
```
... and use:

```cpp
  int x = 2; int y = 10;

  swap(x, y);
```

NB! The argument for a reference parameter must be an *lvalue*

The call swap(x,15); gives the error message

```
invalid initialization of non-const reference of type "int&"
from an rvalue of type 'int'
```

References

▶ A reference is *an alias* for a variable

Variables
Automatic type inference

auto: The compiler deduces the type from the initialization.

Declaration and initialization

```cpp
auto x = 7;                 // int x
auto c = 'c';               // char c
auto b = true;              // bool b
auto d = 7.8;               // double d

std::vector<int> v;
auto it = v.begin();        // std::vector<int>::iterator it

double calc_epsilon();
auto ep = static_cast<float>(calc_epsilon());  // float ep
```

In **float** ep = calc_epsilon(); *the narrowing is not obvious* NB!
with **auto** there is no risk of narrowing type conversion, so using = is safe.

The usual arithmetic conversions

The compiler tries really hard to compile your program.

Example

Do not mix signed and unsigned values!

Statements

Mostly the same syntax as in Java:

- **if**, **switch**
- **for**, **while**, **do while**
- **break**, **continue**

but **goto** *is spelled differently:*

- No **break** to a label
- **goto** (used in C, rarely used in C++)

Operators

Operators and expressions quite similar to Java

The same as in Java

E.g., `+ - * / % ++ -- += -= *=` `&& || & |` etc., and `[]` `.` `?:`

The trinary operator `?:` (like in Java)

```
z = (x>y) ? x : y;
```

```
if (x>y)
    z=x;
else
    z=y;
```

Many more, including

Pointer operators: `* & ->`
Input and output: `<< >>` (*overloaded shift operators*)
`sizeof`, `decltype` (*compile-time*)
