EDAN65: Compilers, Lecture 05 B Abstract grammars

Görel Hedin Revised: 2021-09-13

Abstract grammars

Abstract tree Parse tree Stmt AssignStmt Includes important tokens Includes all tokens Simple natural structure AssignStmt Typed nodes Exp Add Add Exp Exp IdExp **IdExp** IdExp k ; k sum + sum sum sum =

Example: Concrete vs Abstract

Concrete grammar

Abstract grammar

Exp -> Exp "+" Term Exp -> Term Term -> ID

Example: Concrete vs Abstract

Note! Term, Factor, are needed to make the concrete grammar unambiguous.

Note! An abstract grammar has no relation to token sequences, so ambiguity is not an issue. Term and Factor are irrelevant for abstract grammars.

Concrete vs Abstract grammar

	Concrete Grammar	Abstract Grammar
What does it describe?	Describes the concrete text representation of programs	Describes the abstract structure of programs
Main use	Parsing text to trees	Model representing the program inside compiler.
Underlying formalism	Context-free grammar	Recursive data types
What is named?	Only nonterminals (productions are usually anonymous)	Both nonterminals and productions.
What tokens occur in the grammar?	all tokens corresponding to "words" in the text	usually only tokens with values (identifiers, literals)
	Independent of abstract structure	Independent of parser and parser algorithm

Abstract grammar vs. OO model

Abstract grammar	OO model	Other terminology used (algebraic datatypes)
nonterminal	superclass	type, sort
production	subclass	constructor, operator

A canonical abstract grammar corresponds to a two-level class hierarchy!

Example Java implementation

Abstract grammar

Add: Exp -> Exp Exp IdExp: Exp -> ID

abstract class Exp {

class Add extends Exp {
 Exp exp1, exp2;

```
class IdExp extends Exp {
  String ID;
```

JastAdd

- A compiler generation tool. Generates Java code.
- Supports ASTs and modular computations on ASTs.
- JastAdd: "Just add computations to the ast"
- Independent of the parser used.
- Developed at LTH, see http://jastadd.org

JastAdd

- A compiler generation tool. Generates Java code.
- Supports ASTs and modular computations on ASTs.
- JastAdd: "Just add computations to the ast"
- Independent of the parser used.
- Developed at LTH, see http://jastadd.org

JastAdd

- A compiler generation tool. Generates Java code.
- Supports ASTs and modular computations on ASTs.
- JastAdd: "Just add computations to the ast"
- Independent of the parser used.
- Developed at LTH, see http://jastadd.org

JastAdd abstract grammars

[abstract] *Class* [: *Superclass*] ::= *RightHandSide*;

JastAdd abstract grammars

```
[abstract] Class [: Superclass] ::= RightHandSide;
```

```
Program ::= Stmt*;
abstract Stmt;
Assignment : Stmt ::= IdExpr Expr;
IfStmt : Stmt ::= Expr Then:Stmt [Else:Stmt];
abstract Expr;
IdExpr : Expr ::= <ID:String>;
IntExpr : Expr ::= <INT:String>;
BinExpr : Expr ::= Left:Expr Right:Expr;
Add : BinExpr;
```

JastAdd abstract grammars

```
[abstract] Class [: Superclass] ::= RightHandSide;
```

```
Program ::= Stmt*;
abstract Stmt;
Assignment : Stmt ::= IdExpr Expr;
IfStmt : Stmt ::= Expr Then:Stmt [Else:Stmt];
abstract Expr;
IdExpr : Expr ::= <ID:String>;
IntExpr : Expr ::= <INT:String>;
BinExpr : Expr ::= Left:Expr Right:Expr;
Add : BinExpr;
```

Compared to canonical abstract grammars:

- Classes instead of nonterminals and productions
- Classes can be abstract (like in Java)
- Arbitrarily deep inheritance hierarchy (not just two levels)
- Support for optional, list, and token components
- Components can be named
- Right-hand side can be inherited from superclass (see BinExpr).
- No parentheses! You need to name all node classes in the AST.

abstract Stmt;

WhileStmt : Stmt ::= Cond:Expr Stmt;

abstract Stmt;

WhileStmt : Stmt ::= Cond:Expr Stmt;

```
abstract class Stmt extends ASTNode {}
```

```
class WhileStmt extends Stmt {
   Expr getCond();
   Stmt getStmt();
```

abstract Stmt; WhileStmt : Stmt ::= Cond:Expr Stmt;

```
abstract class Stmt extends ASTNode {}
```

```
class WhileStmt extends Stmt {
   Expr getCond();
   Stmt getStmt();
```

- A general class ASTNode is used as implicit superclass.
- A traversal API with *get* methods is generated.
- If component names are given, they are used in the API (getCond).
- Otherwise the type names are used (getStmt).

The list is represented by a List object that can be used as an iterator:

```
Program p = ...;
for (Stmt s : p.getStmts()) {
    ...
}
```

Program ::= Stmt*; Example AST Program getStmts() class Program extends ASTNode { int getNumStmt(); // 0 if empty Stmt getStmt(int i); // numbered from 0 List<Stmt> getStmts(); // iterator } Example AST Program

The list is represented by a List object that can be used as an iterator:

```
Program p = ...;
for (Stmt s : p.getStmts()) {
    ...
}
```

Or access a specific statement:

```
Program p = ...;
if (p.getNumStmt() >= 1) {
    Stmt s = p.getStmt(0);
    ...
}
```

Program ::= Stmt*; Example AST Program getStmts() class Program extends ASTNode { int getNumStmt(); // 0 if empty Stmt getStmt(int i); // numbered from 0 List<Stmt> getStmts(); // iterator } Example AST Program

The list is represented by a List object that can be used as an iterator:

```
Program p = ...;
for (Stmt s : p.getStmts()) {
    ...
}
```

Or access a specific statement:

```
Program p = ...;
if (p.getNumStmt() >= 1) {
    Stmt s = p.getStmt(0);
    ...
}
```

Note! List is a JastAdd-specific class (like ASTNode and Opt). It is *not* the same class as java.util.List.

Generated Java API, optionals

Example AST

• The traversal API includes a *has* method for the optional component.

General traversal

Will stop also at Opt and List nodes.

Can be used for general traversal of the children of a node.

```
class ASTNode {
    Iterable astChildren(); //Iterator for the children
```

```
void ASTNode.m() {
```

```
...
for (ASTNode child : astChildren()) { ... }
}
```

Low-level traversal API

Will stop also at Opt and List nodes.

This low-level API is not recommended.

Use iterator or high-level API instead – much more readable.

```
class ASTNode {
    int getNumChild();
    ASTNode getChild(int i);
    ASTNode getParent(); // null for the root
}
```

Connection to Beaver

Beaver spec

Defining an abstract grammar

This is object-oriented modeling!

- What kinds of objects are there in the AST? E.g., Program, WhileStmt, Assignment, Add, ...
- What are the generalized concepts (abstract classes)? E.g., Statement, Expression, ...
- What are the components of an object?
 E.g., an Assignment has an Identifier and an Expression...

Defining an abstract grammar

This is object-oriented modeling!

- What kinds of objects are there in the AST? E.g., Program, WhileStmt, Assignment, Add, ...
- What are the generalized concepts (abstract classes)? E.g., Statement, Expression, ...
- What are the components of an object?
 E.g., an Assignment has an Identifier and an Expression...

Program ::= ...; abstract Statement; abstract Expression; WhileStmt : Statement ::= ...; Assignment : Statement ::= Identifier Expression; ...

Use good names!

when you write	the following should make sense
A : B ::=	An A is a special kind of B
C ::= D E F	A C has a D, an E, and an F
D ::= X:E Y:E	A D has one E called X and another E called Y
G ::= [H]	A G may <i>have</i> an H
J ::= <k:t></k:t>	A J has a K token of type T
L ::= M*	An L <i>has</i> zero or more Ms

Use good names!

when you write	the following should make sense
A : B ::=	An A is a special kind of B
C ::= D E F	A C has a D, an E, and an F
D ::= X:E Y:E	A D has one E called X and another E called Y
G ::= [H]	A G may <i>have</i> an H
J ::= <k:t></k:t>	A J has a K token of type T
L ::= M*	An L <i>has</i> zero or more Ms

Examples of bad naming (from inexperienced programmers)	Good naming
A ::= [OptParam];	A ::= [Param];
OptParam ::= Name Type;	Param ::= Name Type;
A ::= Stmts*;	A ::= Stmt*;
abstract Stmts;	abstract Stmt;
While : Stmts ::= Exp Stmts;	While : Stmt ::= Exp Stmt;

Design simple abstract grammars!

- Abstract grammars should be clear and simple
- Don't let parsing details creep into the abstract grammar

Design simple abstract grammars!

- Abstract grammars should be clear and simple
- Don't let parsing details creep into the abstract grammar

Bad abstract grammar (parsing inspired)	Good abstract grammar (simple, conceptual)
A ::= First:B Rest:B*	A ::= B*
Add : Exp ::= Left:Exp Right:Term	Add : Exp ::= Left:Exp Right:Exp

Design simple abstract grammars!

- Abstract grammars should be clear and simple
- Don't let parsing details creep into the abstract grammar

Bad abstract grammar (parsing inspired)	Good abstract grammar (simple, conceptual)
A ::= First:B Rest:B*	A ::= B*
Add : Exp ::= Left:Exp Right:Term	Add : Exp ::= Left:Exp Right:Exp

- "At least one child" can easily be checked by a semantic check. Don't impose a more complex structure just to check this.
- Term, Factor, etc. is a parsing issue. Don't put Term and Factor in your abstract grammar!!

Design a parsing grammar

- Design the abstract grammar first.
- Then design a high-level concrete grammar, making it as similar as possible to the abstract grammar.
 - Replace inheritance with alternative productions
 - The grammar will probably be ambiguous
- Then design a low-level concrete grammar, suitable for a particular parsing algorithm/tool.

For Beaver:

- Eliminate ambiguities
- Eliminate repetition and optionals (will make it easier to construct the AST)

Semantic actions in parsers

Semantic actions in parsers

- Code that is added to a parser, to perform actions during parsing.
- Usually, to build the AST.
- Old-style 1-pass compilers did the whole compilation as semantic actions.
- Parser generators support semantic actions in the parser specification.

Beaver example

Abstract grammar

abstract Stmt; IfStmt : Stmt ::= Expr Stmt; Assignment : Stmt ::= IdExpr Expr; IdExpr : Expr ::= <ID:String>;

High-level CFG

stmt -> ifStmt | assignment
ifStmt -> IF "(" expr ")" stmt
assignment -> ID ASSIGN expr ";"

Beaver example

Abstract grammar

abstract Stmt; IfStmt : Stmt ::= Expr Stmt; Assignment : Stmt ::= IdExpr Expr; IdExpr : Expr ::= <ID:String>;

High-level CFG

stmt -> ifStmt | assignment
ifStmt -> IF "(" expr ")" stmt
assignment -> ID ASSIGN expr ";"

beaver spec without semantic actions:

%class "LangParser"; %package "lang"; ... %terminals IF, LPAREN, RPAREN, ID, ASSIGN, SEMICOLON; %goal stmt; // The start symbol // Context-free grammar stmt = ifStmt | assignment; ifStmt = IF LPAREN expr RPAREN stmt; assignment = ID ASSIGN expr SEMICOLON;

Beaver example

beaver spec with semantic actions:	abstract Stmt; IfStmt : Stmt ::= Expr Stmt;
%class "LangParser";	Assignment : Stmt ::= IdExpr Exp
%package "lang";	IdExpr : Expr ::= <id:string>;</id:string>
 %terminals IF, LPAREN, RPAREN, ID, ASSIGN, SEMIC	COLON;
%goal stmt; // The start symbol	
%typeof stmt = "Stmt";	
%typeof ifStmt = "IfStmt";	
%typeof assignment = "Assignment";	
// Context-free grammar	
stmt = ifStmt assignment;	
ifStmt = IF LPAREN expr.e RPAREN stmt.s {: return n	new lfStmt(e, s); :} ;
assignment =	
ID.id ASSIGN expr.e SEMICOLON {: return new As	<pre>ssignment(new IdExpr(id),e); :};</pre>

Abstract grammar

Expr;

atura at Cturat

semantic actions build the trees

variables capture token strings and subtrees for nonterminals the nonterminals return objects of the abstract grammar classes

Summary questions: Abstract syntax trees

- What is the difference between an abstract and a concrete syntax tree?
- What is the difference between an abstract and a concrete grammar?
- What is the correspondence between an abstract grammar and an objectoriented model?
- Orientation about JastAdd abstract grammars, traversal API, and connection to Beaver.
- What are properties of a good abstract grammar?
- What is a "semantic action"?
- How can Beaver be used for building ASTs?
